INTRODUCTION

This application note describes a Microchip system solution for a low end/power wireless home security system. This design implements an HCS200 encoder for the intruder sensor signal encryption, one PIC12C508A PICmicro® for sensor monitoring and RF signal initiation, HCS515 decoders for decrypting the received intruder sensor signal and a PIC16C77 PICmicro for base station panel monitoring and control. Other support logic is included, such as a battery back-up circuit, simple single stage lead acid battery charger and external siren control, but the focus of the application is the implementation of Microchip KEELOQ® and PICmicro products for a complete solution.

APPLICATIONS

Applications implementing low power RF wireless systems are entering the marketplace with ever increasing acceptance, fueled in part by growing awareness of the consumer. Low power wireless systems usually transmit less than 1mW of power and do not require user licenses for operation. These systems operate over distances of 5 to 100 meters, depending on the application.

Wireless systems are being implemented in the automotive, residential, personal and commercial arenas with increasing growth rates every year. Wireless systems in these areas include, but are not limited to: vehicle alarm arming and disarming, home garage and gate door openers, home lighting control, home security and fire alarm systems, pagers, cellular phones, utility meters for near-field readings, warehouse inventory control systems and RF LANs.

In many of these applications, different levels of security are required. The level of security required is dependent on the application and customer demands. For instance, a warehouse inventory control or utility meter system may require little or no security features whereas automobile access and home security alarm systems will require more.

No matter what level of security features are implemented, one vulnerable link in low power RF wireless based security systems is the actual RF signal itself. An RF based system could allow for the would-be intruder/thief to use a code scanning or a code grabbing system to possibly gain unauthorized access to the home, car or other less secure system.

Code scanning is an effective tool for the would-be thief on systems with limited number of possible code combinations which are found in quite a number of remote control systems. Patience, time and a hand-held microprocessor based system are all the intruder would need.

Code grabbing is a far easier way of gaining unauthorized access. In this method, the thief would monitor and capture the RF signal used in opening the home garage door or car. The thief would then wait until an opportune moment and then retransmit this code to gain access.

It is apparent that secure remote control systems can be implemented, if two conditions are met. The KEELOQ code hopping system meets both these conditions with ease.

1. A large number of possible combinations must be available.
   A 66-bit transmission code is used to make scanning impossible. The 32-bit encrypted portion provides for more than 4 billion code combinations. A complete scan would take 17 years! If the 34-bit fixed portion is taken into account, the time required for a complete scan jumps to 5,600 billion years.

2. The system may never respond twice to the same transmitted code.
   The random code algorithm will never respond to the same code twice over several lifetimes of a typical system.

Every time a remote control button is pushed, the system will transmit a different code. These codes appear random to an outsider, therefore, there is no apparent relationship between any code and the previous or next code.

For more information on code scanning, code grabbing and an introduction to KEELOQ Code Hopping, see Technical Brief TB003, titled "An Introduction to KEELOQ Code Hopping". Refer to the Secure Data
AN714

Products Handbook, Microchip document number DS40168 for additional information on Keeloq® products.

With the arrival of the Microchip Keeloq code hopping security products, secure remote control systems can be implemented. Microchip provides a complete security solution with a full range of encoders and decoders that incorporate the Company’s patented Keeloq code hopping technology algorithm, allowing you to get the most advanced security technology. Keeloq encoders are designed to be the transmitters and Keeloq decoders, the receiver of secure remote keyless entry (RKE) systems.

The Keeloq encoders feature on-chip, error corrected EEPROM for non-volatile operation and, therefore, reduce the required components normally external to the encoder. The only additional circuitry required are push buttons, battery and RF circuitry. The Keeloq decoders are single-chip solutions that employ normal and secure learning mechanisms, and operate over a wide voltage range. Microchip decoders are also full-featured with serial interface to PICmicro microcontrollers, allowing designers to integrate the decoder with system functionality.

SYSTEM OVERVIEW

The Microchip Keeloq solution is being implemented into more and more systems requiring proven security. Systems such as, but not limited to:

- Automotive security
- Gate and garage door openers
- Identity tokens
- Software protection
- Commuter access
- Industrial tagging
- Livestock tagging
- Parking access
- Secure communications
- Residential security

One simple example implementing the Keeloq solution is a home security system. The home security system described herein utilizes Keeloq code hopping security products and a PICmicro microcontroller.

Some specific system design goals for this low end/low power security system were:

- Wireless solution
- Secure RF transmissions
- Battery operation of intruder sensors for a minimum of 1.5 years
- Sensor module flexibility to operate with various off-the-shelf switches for doors and windows
- Microcontroller based system
- Battery back-up system which provided for up to 10 hours of operation at a load draw of 400mA

- System remote arm and disarm by means of the existing garage door opener (not completely implemented in the current release)

The three main hardware components, which comprise this home security system are, the Base Station Panel, Intruder Sensor Modules and the Battery Charger/Accessory Unit.

SYSTEM DESCRIPTION

The following sections provide a greater in depth look into each of the three main hardware components.

BASE STATION PANEL

The home security base station panel provides for:

- Monitoring of sensor module initiated RF signals
- User interface and system setup via the 4x4 keypad
- Visual feedback via the 2x16 character Liquid Crystal Display (LCD) module
- On-board piezo buzzer control
- Real-time clock
- Monitoring of a single stage battery charger unit
- Automatic DC power selection circuit

The base station can be functionally divided into 4 main components:

1. Keeloq HCS515 decoder interface.
2. Power supply switching circuit.
3. Battery charger unit monitoring.
4. LCD and 4x4 keypad interface.

Base Station Operation

One of the more important tasks the base station’s microcontroller (PIC16C77) must handle, is to monitor and process the output data of the two HCS515 decoders. Each decoder is capable of learning up to seven sensor modules or “zones”. Within each zone, there are four different message types which the PIC16C77 must decode and process (See Appendix A, Figure 6 for the following text description).

For example, a sensor module may send an alarm, okay, test or learn transmission. In turn, the PIC16C77 reads the data (up to 80-bits) from the HCS515 decoder, evaluates the message contents and initiates the appropriate action. If an alarm condition occurs, the external siren will be activated and the internal panel piezo buzzer, (BZ1) will sound, if enabled. For any valid signal reception, such as a test, learn, sensor okay condition or alarm transmission, the history profile for that sensor module will be updated. This update consists of a time stamp and the sensor’s module battery status. If the sensor battery status indicates a low battery state, then the base panel piezo buzzer will beep (if enabled) four times every minute until the condition is resolved. The user can determine which sensor module battery is low through proper keypad selections and individual zone battery status displayed on the LCD.
The base station can be placed into a “learn” mode so as to learn up to seven sensors (zones). Through proper keypad selections, the PICmicro commands the HCS515 decoder into the learn mode. (See Figure 1 and Table 1). Once placed in this mode, two consecutive transmissions by the sensor are required to complete a successful learn. Once a sensor is learned, a “key” name for that zone must be selected. A menu will automatically appear on the LCD for this selection process. Currently up to 15 different key names are available to choose from. The selected key name is then stored in the HCS515 EE user space.

The history profile of each sensor is written to the available user EEPROM in the HCS515 decoder. The total EEPROM data space available in the HCS515 is 2kbits. System data space is 1kbits and user memory space is the remaining 1kbits. System data space is not accessible by the user (See Table 2 for the user EEPROM memory map). The demodulated data input into the decoders is obtained from a super regenerative data receiver referenced RF1 (See Appendix A, Figure 7, Part Number RR3-433.92 - Manufactured by Telecontrol). The receiver has a typical RF sensitivity of -105dBm and consumes 3mA, maximum.

A Microchip microcontroller supervisory circuit, MCP130-475, is used to ensure the required system panel operating voltage range is adhered to. The brown-out feature on the PIC16C77 was not used since the system's base panel operating voltage range is 4.5 to 5.5V.

The base station panel is designed to operate from one of two available DC input sources: the converted AC line power or the 12V lead-acid battery back-up (See Appendix A, Figure 5 for the following text description). Both DC sources are fed into the panel via connector, JP1. From JP1, each source is input to a separate adjustable voltage regulator. The primary DC source regulator, U2, has its Vout set to 5.05VDC, while the secondary DC source regulator, U3, has its Vout set to 5.05VDC. Both regulator outputs are fed into separate inputs of the automatic battery back-up switch, U1.

Switch U1, is an 8-pin monolithic CMOS I.C. which senses the DC level of the two input sources and connects the supply of the greater potential to its output, pin 1. This is a break-before-make switch action and switching typically occurs in 50μs. Capacitor C9 is used to minimize the switching transient during the transition.

One limitation of the switch is its current switching capabilities. Maximum continuous current of the switch is exceeded by this panel design so two PNP transistors were added which provides for greater power switching.

The implementation of the PNP transistors is such that when the primary source is the greater of the two, Q3 will be biased into saturation and Q1 will be off. In either state, the load is handled through the transistors and the “VO” pin of U1 is no longer required. However, the “VO” pin is configured for driving LEDs, which indicate the DC source selected.

The PIC16C77 receives status back relating to the switch selection via the signal labeled “PSOURCE”. The state of this feedback signal is active low when the primary DC source is selected, and active high if the secondary source is selected.

This power switching circuit also allows for the PIC16C77 to select the secondary source, even if the primary source is present. If the signal labeled “BAT-SEL” is asserted high by the PIC16C77, NPN transistor Q2 will be turned on and effectively reduce Vout of U2 to 1.25VDC. U1 will detect the drop and switch to the backup source. This feature can be used as a test-mechanism. Finally, Vref of U3 supplies the voltage reference, VREF, for the Analog-to-Digital module on the PIC16C77. This signal is labeled “VBAT”.

As with any home security system, it is important to provide for backup power in the event of a primary source failure. A simple single stage back-up charger unit is provided for this requirement. Based upon a load draw of 400mA, 10 hours of operation are provided for. This is a worse case scenario, which includes a 170mA (typical) current draw from the external siren.

The PIC16C77 samples the battery voltage, once per minute. If the sampled battery voltage is less than ~12.75VDC, then the current limit resistor, R15, is switched in or if Vout >12.75VDC, then bypassed (See Appendix A, Figure 9 and Appendix A, Figure 10). The user can view the battery voltage on the LCD by pressing the appropriate keys on the 4x4 keypad. (See Table 1).

The system LCD and 4x4 keypad provide for system status feedback and setup. Status information, such as sensor module battery state, zone faults and time-of-day are displayed on the 2x16 character LCD. The LCD is updated by the PIC16C77 through data transfers on PORTD (See Appendix A, Figure 6 and Appendix A, Figure 7).

System parameter setup such as enabling the internal piezo buzzer, time-of-day setup, zone naming and alarm initiating is provided through the 4x4 keypad. System test modes are also entered through the keypad. The keypad is interfaced to PORTB which utilizes the interrupt on change feature.

A 32.768KHz watch crystal is connected to the Timer1 external oscillator pins for the generation of a real time clock. Specific system data, such as alarm time, battery on/off cycle time and all valid decoded RF signals are time-tagged. The clock time is setup/changed via the 4x4 keypad and operates using the military time format, i.e., 2:30PM will display as 14:30:00, while 2:30AM will display as 02:30:00.

**INTRUDER SENSOR MODULE**

The four main functions of the intruder sensor modules are:

1. Intruder detection.
2. Sensor battery status.

For each of these functions, an input to the HCS200 KEELOQ encoder is asserted (active high) by the PIC12C508A. The end result is a 66-bit encrypted code word transmission, via RF, to the base station panel for decryption and processing.

In order to provide for these functions, additional logic is implemented to complement the HCS200 encoder. The logic consists of a PIC12C508A microcontroller, a relaxation type oscillator circuit, N-channel MOSFET for signal level translation, Colpitts oscillator used for the Amplitude Shift Keying (ASK) transmitter, and a few additional passive components.

See Appendix A, Figure 11 and Figure 12 for the following sensor operation discussion.

One important operational requirement of the sensor module besides reliable signal decoding and secure RF transmission, is low current consumption. With the components selected, sensor battery life is calculated to be a minimum of 1.5 years.

**Sensor operation**

The KEELOQ HCS200 encoder is a perfect fit for implementation into the sensor modules. The HCS200 encoder provides for:

**Security**

- Programmable 28-bit serial number
- Programmable 64-bit encryption key
- Each transmission is unique
- 66-bit transmission code length
- 32-bit hopping code
- 28-bit serial number, 4-bit function code, VLOW indicator transmitted
- Encryption keys are read protected

**Operating**

- 3.5–13.0V operation
- Three button inputs
- Seven functions available
- Selectable baud rate
- Automatic code word completion
- Battery low signal transmitted to receiver
- Non-volatile synchronization data

**Other**

- Easy to use programming interface
- On-chip EEPROM
- On-chip oscillator and timing components
- Button inputs have internal pulldown resistors

The HCS200 combines a 32-bit hopping code generated by a powerful non-linear encryption algorithm, with a 28-bit serial number and 6 information bits to create a 66-bit transmission stream. The length of the transmission eliminates the threat of code scanning and the code hopping mechanism makes each transmission unique, thus rendering code capture-and-resend schemes useless. (See Figure 2, Figure 3 and Figure 4 for code word organization and formats).

The encryption key, serial number and configuration data are stored in EEPROM, which is not accessible via any external connection. This makes the HCS200 a very secure unit.

The HCS200 responds to input signals initiated by the PIC12C508A. The PIC12C508A provides for the sensor signal detection and decoding and RF signal initiation. The PIC12C508A is configured to operate on the internal RC oscillator with the wake-up on pin change feature enabled. The PIC12C508A is placed in the “sleep” mode for about 99% of the time, based on the overall repeated time period of 1.5 hrs (discussed later). While the wake-up on pin change feature is utilized, the internal weak pull-ups are disabled and larger ohmic external resistors are used. This reduces the current consumption, while retaining the wake-up on pin change feature.

Since the HCS200 and RF circuitry are only required after the PIC12C508A awakens by a pin state change and with the requirement to reduce additional current draw from the battery, the HCS200 and RF circuitry are powered through I/O pin, GP5. The current sourcing capability of the PIC12C508A is sufficient for this requirement. This configuration reduces the overall current draw by 1µA (typically) during sleep mode.

The PIC12C508A detects and responds to one of the four input pin state changes, which are:

1. Intruder sensor activation on input pin GP3 (active high).
2. Sensor test transmission activated by switch closure on input pin GP1 (active high).
3. Sensor learn transmission activated by switch closure on input pin GP1 (active high).
4. 1.5 hr timing cycle on input pin GP0 (active high). This signal is used to generate a sensor battery status transmission.

Once the wake-up signal has been decoded, the HCS200 and RF circuitry are powered-up via pin GP5 labeled ‘CNTPWR’. (See Appendix A, Figure 11 and Figure 12). A 3µs delay is allowed for power-up stabilization and then the PIC12C508A asserts an active high signal to U2 inputs S0, S1 or both, depending on the wake-up signal decoded. The HCS200 input pin states are as follows:

1. Pin S0 asserted only - alarm condition.
2. Pin S1 asserted only - 1.5 hr elapsed time sensor update.
3. Pin S0 and S1 asserted simultaneously, Learn or test mode entered.

The alarm condition is in response to a possible intruder detection at the door or window. The switches used for monitoring door and window access are FORM C and SPST type, respectively. The FORM C door switches are specifically designed for steel skin doors, but are well suited for use in wooden doors. SENTROL, INC manufactures both switch types used.

If the sensor is used for a door or window, it is open. For a window application, JP2 is closed and JP1 is open. These jumpers can be used for implementing different resistor values, based upon the sensor switch implemented.

It is imperative that the correct switches are specified to eliminate a source of false alarm conditions. Items such as door to frame gap and door material construction contribute a big part in selecting the appropriate switch sensor.

The 1.5 hr elapsed time sensor update is developed using a relaxation timing circuit. The timing circuit consists of a JFET configured as a constant current source set to 400nA, a Programmable Unijunction Transistor (PUT), an N-channel MOSFET for signal level translation and a reverse biased diode to reduce PUT discharging time.

This timing circuit is configured to produce a state change on pin GP0 approximately every 100 seconds. The constant current source charges up the low leakage 1µF capacitor, C1. When the voltage across C1 equals the firing voltage of the PUT, which is the peak point emitter voltage termed Vp, and if the current is large enough, the PUT will enter into the negative resistance region and begin to discharge. The maximum firing current required by the 2N6028 for a RG value = 1M is 150nA. RG = (R2*R3)/(R2+R3).

Resistors R2 and R3 set the voltage Vp. This voltage is Vp = ~(VBat * R2)/(R2 + R3). Diode D1, which is reversed biased during the PIC12C508A sleep period is used to reduce the PUT discharging time period. When the PIC12C508A wakes from sleep, diode D1 is forward biased and provides a low impedance path to ground for C1 discharge (See Appendix A, Figure 11). When the diode is not used, the discharge period was observed to be about 7-8ms. With the diode, the discharge time period was reduced to tens of microseconds. The savings of several milliseconds, reduces the time the PIC12C508A is awake and therefore helps to extend the battery life of the sensor module.

The N-channel MOSFET, Q2, provides for signal level translation from the PUT. If the voltage level set by resistors R2 and R3 (~4Vdc for new batteries) is applied directly to pin GP0, additional current consumption would be realized, since this voltage on a Complimentary Metal Oxide Semiconductor (CMOS) input would be near its threshold.

The N-channel MOSFET is configured as a switch, such that the drain channel is tied to VBat through a 6.8Mohm resistor and the source channel is grounded. Then, by tying the drain channel to pin GP0, the voltage on GP0 is either VBat or ground, depending on the PUT state applied to the gate of Q2.

Changing the R2 to R3 ratio could increase voltage, Vp. If the voltage level was set such that it falls outside the CMOS input threshold, then Q2 and R1 could be eliminated.
When the PIC12C508A wakes from sleep, it increments a counter variable and then returns to sleep. This process repeats until the counter variable equals 54, which equates to approximately 1.5 hrs. At this 1.5 hr time cycle, the PIC12C508A initiates an ‘OKAY’ signal. This signal is received and decoded by the base panel for determining the state of the sensor module battery.

The PIC12C508A then resets the cycle count variable to zero and starts the time cycle process over again. Since the battery status is embedded into all 66-bit code word transmissions, if an alarm, learn or test condition is activated, the counter variable will also be reset to zero.

A test or learn transmission is initiated if switch S1 is depressed. The learn sequence will be recognized if the base station is placed in the learn mode. In either case, the switch closure wakes the PIC12C508A from sleep. The PIC12C508A then decodes the inputs and asserts the proper signals on the S0 and S1 pins of the HCS200.

With any RF link, noise is an issue that must be considered. There are some ways to control transmission integrity such as error detection/correction algorithms, repeated transmissions (simplex mode - one way) or with high end systems, the master queues each sensor for a transmission (half-duplex). The system described in this application note is configured for the simplex mode of operation and implements repeated signal transmissions for alarm conditions.

As the number of sensor modules installed in the home increases, 14 possible with this design, the odds increase that two or more sensors may converge in time for initiating a transmission cycle. The result would be a RF signal collision at the receiver and most likely all data would be lost. Once this condition occurs and since the time base for each system is not at the exact same frequency, they will typically diverge until the next occurrence.

The time base for the sensor module is the PIC12C508A which is clocked internally by the on-chip RC oscillator operating at ~ 4 MHz.

While the sensor module initiates up to four different RF transmission cycles, the most important one is the alarm condition. If the PIC12C508A detects an alarm condition, repeated RF transmissions are sent to ensure the base station receives the alarm signal. In the event that an ‘OKAY’ signal transmission from sensor module A and an alarm transmission from sensor module B occur at the exact same time, the alarm transmission will be received because of repeated alarm transmissions. The ‘OKAY’ signal only sends 1 code word transmission, while the alarm condition results in up to 5 code words transmitted.

The simple RF circuit implemented in the sensor module is an Amplitude Shift Keying (ASK) type consisting of a Colpitts oscillator with a SAW resonator. The resonator provides for a stable resonant frequency of 433.92 MHz (See Appendix A, Figure 12).

The PWM data output of the HCS200 encoder is applied to the base of the Colpitts oscillator and therefore amplitude modulates the carrier by turning the carrier on/off. The data rate is typically 833 bps.

**SENSOR MODULE BATTERY CAPACITY CALCULATIONS**

Before the expected battery life of the sensor module can be calculated, an operational cyclic time period must be defined. The cyclic period for the sensor module is composed of three distinct operational states: sleep, housekeeping and intentional radiation. These three states repeat on a continual basis, therefore, creating an operational cyclic profile. The profile is then used to calculate the battery capacity requirements.

For the sensor module, the cyclic time interval is approximately 1.5 hours. During this 1.5 hours, the PIC12C508A is placed in sleep 54 times. Of these 54 times, the processor wakes-up from sleep 53 times to perform some minor housekeeping and on the 54th wake-up from sleep, the intentional radiation state is executed. This is the “OK” transmission.

There is also the power-up state. This state is only executed once (initial power-up), and exhibits no significant impact on the overall battery life.

The active times for each of these states is defined below. The processor wake-up time from sleep (typical 400µs) is included in the two wake-up states.

**Timing states known:**
- Sleep state - typical 100 seconds (each occurrence)
- Housekeeping state – typical 56 ms (each occurrence)
- Intentional radiation state – typical 700 ms (each occurrence)

Therefore, cyclic time period is:

\[= (54 \times 100s) + (53 \times 56mS) + 700mS\]

\[= 5403.7 \text{ seconds}\]

\[= 1.5010 \text{ hours}\]
Current consumption variables known:
Sleep state current consumption:
  • 3.2\(\mu\)A @ 6.4V\text{DC} (new batteries)
  • 2.0\(\mu\)A @ 3.3V\text{DC} (battery EOL)
Housekeeping state current consumption:
  • 0.70mA @ 6.4V\text{DC}
  • 0.30mA @ 3.3V\text{DC}
Intentional radiation state current consumption:
  • 4.64mA peak @ 6.4V\text{DC}
  • 2.22mA peak @ 3.3V\text{DC}

With these operational parameters known, we can now calculate the expected battery life respective to new battery voltage. It should be noted that this is the worst case scenario and the actual battery capacity required may be less.

Calculate As Follows:
1. Calculate the percentage of time spent in each state relative to the overall cyclic time period.
   Sleep state%:
   • \((5400s/5403.7s) \times 100 = 99.932\%\)
   Housekeeping state%:
   • \((2.9680s/5403.7s) \times 100 = 0.054925\%\)
   Intentional radiation state%:
   • \((700mS/5403.7s) \times 100 = 0.054925\%\)
2. Calculate the number of hours in 18 and 24 months.
   • 18 months (547.5 days) \times 24hrs/day = 13,140 hours
   • 24 months (730 days) \times 24hrs/day = 17,520 hours
3. With the hours, percentages and current variables known the battery capacity required for the sensor module can be developed.

For 18 months:
Sleep state:
• 13,140 hours \times 99.932\% \times 3.2\mu\text{A} = 42mAh
Housekeeping state:
• 13,140 hours \times 0.054925\% \times 0.70mA = 5.052mAh
Intentional radiation state:
• 13,140 hours \times 0.012954\% \times 4.64mA = 7.899mAh
Total battery capacity required = 54.95mAh

For 24 months:
Sleep state:
• 17,520 hours \times 99.932\% \times 3.2\mu\text{A} = 56.02mAh
Housekeeping state:
• 17,520 hours \times 0.054925\% \times 0.70mA = 6.736mAh

Intentional radiation state:
• 17,520 hours \times 0.012954\% \times 4.64mA = 10.530mAh
Total battery capacity required = 73.29mAh

From these calculations, we can see that if the desired operational life of the sensors is 1.5 years, the battery capacity would need to be ~55mAh. It is noted that these calculations do not take into consideration the operational characteristics of the batteries such as leakage and self discharge.

BATTERY CHARGER/ACCESSORY UNIT
The battery charger/accessory unit provides for system back-up power in the event of primary power loss. Approximately 10 hours of system operation is provided with battery operation. This unit also contains some system peripheral circuitry and is divided into 4 main components:
1. Single stage constant voltage (constant potential) battery charger.
2. Enclosure door tamper switch feedback.
3. External piezo siren drive.
4. System remote arm/disarm using existing garage door opener. (currently not fully implemented)

Theory of Operation
The single stage battery charger consists of an adjustable voltage regulator, U1, operational amplifiers (op-amp) U2 and U3, P-channel MOSFET Q4, NPN transistor Q6, current limit resistor R15, and Schottky diode D1 (See Appendix A, Figure 9 and Figure 10). The battery used in this system is a NP4-12 Yuasa-Exide lead acid type.

The standby (float) service is a battery operational state where a constant voltage is maintained on the battery, until the battery is called on to discharge. In this system, a constant voltage (constant potential) charging circuit is implemented to generate this maintenance voltage. The manufacturer recommends a 2.3 volts/cell maintenance voltage during this float mode. This equates to a total maintenance voltage requirement of 13.8 volts. In the event of a deep discharge cycle, the initial charging current could approach 8 amps (2CA). For this application, the initial charging current is limited to approximately 630 mA (.16CA) When charging at 2.30 volts/cell, charging current at the final stage of charging will drop to as little as 0.002CA.

During the charge cycle, the charge current will decrease and the battery voltage will increase. When the battery voltage approaches 12.75V\text{DC}, the current limit resistor will be switched out of the charge loop through turning on Q6. This will shorten the remaining battery recovery time.
NP batteries are designed to operate in standby service for approximately 5 years based upon a normal service condition, in which float charge voltage is maintained between 2.25 and 2.30 volts per cell in an ambient temperature of approximately 20°C (68°F).

In general, to assure optimum battery life, a temperature compensated charger is recommended. If the operational temperature range is between 5°C to 40°C (41°F to 104°F), it is not necessary to provide a temperature compensation function. If a temperature compensated charger is not implemented, the manufacturer recommends the maintenance voltage be set to a voltage which closely reflects the average ambient temperature based upon a compensation factor of -3mV/°C for standby (float) use.

For example:
Standard center point voltage temperature is:
- 13.8 volts @ 20°C.

Estimated average temperature is:
- 29.44°C (~85°F).

Compensated charging voltage is:
- 13.8 volts + (-3mV (29.44° - 20°)) = 13.772 volts.

For this design, the battery maintenance voltage is set to 13.77 volts. Adjustable voltage regulator, U1, is adjusted to approximately 14.00V_{DC}. This voltage accounts for the forward voltage drop of diode, D1.

This charging circuit is operating in an open loop configuration in the sense that the regulator output is manually set. If a voltage trim is required, potentiometer R18, must be adjusted.

In order to provide for some feedback to the base panel controller, a differential amplifier is configured with op-amps, U2 and U3. This amplifier configuration is such that a reference 5.1V zener voltage is subtracted from the battery voltage. This difference is amplified and routed to TB1, pin 7. The PIC16C77 base station controller will periodically sample this voltage. If this voltage falls outside the required battery maintenance voltage, then the PIC16C77 will indicate such on the LCD and an adjustment will be required.

An airflow fan is implemented in the accessory enclosure to dissipate any gases generated by the battery and provide for moderate enclosure cooling. Air inlet and exhaust ports are provided in the enclosure. The steel enclosure dimensions are 10Hx8Wx4D. The fan current draw is approximately 100 mA @ 12V_{DC}.

For added security, an enclosure door tamper switch is utilized. If the enclosure door is opened, the PIC16C77 will be notified at pin RA2 and an alarm sequence is initiated, if the system is armed. This switch is interfaced to TB5, pins 1 and 2. While the enclosure door is closed, the feedback signal developed across R3 is active low; else if the enclosure door is opened, an active high signal is observed across R3.

In the event that an alarm condition has been initiated, the base station PIC16C77 controller will turn on NPN transistor, Q1. When Q1 is on, its collector junction will be switched to ground, and this state will turn on Q3. The drain channel of Q3 is connected to TB2, pin 1 through a 56-ohm/10W current limit resistor for direct connection to the external piezo siren. The siren implemented operates at 12V_{DC}, typically, with a current draw of ~170mA while exhibiting a ~116dBm sound pressure level annunciation. This circuit can be easily modified to allow for additional current draw should a louder siren be desired.

An eight conductor overall shielded cable provides the interface link between the base station panel and the battery charger/accessory unit.

This system also allows for an existing garage door system to arm and disarm the security system. (This feature is not completely implemented at this time)

REGULATORY CONSIDERATIONS

While low power wireless products do not need to be individually licensed, they are subject to regulation. Before low power wireless systems can be marketed in most countries, they must be certified to comply with specific technical regulations. In the U.S., the FCC issues certification. In the U.K., it is DTI, in Germany it is the FTZ, and so on.

FCC Compliance

It is noted here that Microchip Technology Incorporated does not guarantee compliance with any FCC or other regulatory requirements for this home security system, although FCC guidelines were followed and adhered to, when possible. It is the responsibility of the designer to ensure that the design is compliant to local standards.

SUMMARY

Automobile, Home or Office. All aspects of today’s daily life require security. Consumers have a key pad in their hand, a security keypad on their wall and a smart card to get in the door.

The KEELOGO family of patented code hopping devices has quickly become the world standard for security applications by providing a simple yet highly secure solution for remote control locking devices, house keys, garage door openers, and home security.

From the low-cost, low-end HCS200 encoder to the high-end HCS410 encoder and transponder, Microchip’s KEELOGO code hopping solutions incorporate high security, a small package outline, and low cost - an ideal combination for multifunctional, unidirectional remote keyless entry (RKE) systems. For logical and physical access control applications, such as cellular phones and smart cards, the KEELOGO family offers convenience and security in one package.
Microchip provides a complete security solution with a full range of encoders and decoders that incorporate the Company’s patented KEELOO code hopping algorithm, allowing you to get the most advanced security technology for practically a steal.

As with all security systems, it is important that the end user understand the level of security, which is required for the assets you are wanting to protect. The strength of the system is only as strong as the weakest link. Microchips KEELOO Security devices are proven not be a weak link.

Note: Information contained in the application note regarding device applications and the like is intended through suggestion only and may be superseded by updates. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise.

APPENDIX C: SENSOR MODULE CODE FILES

Wireless Home Security with Keeloq and the PICmicro

Filename: sensor08.c
Data: 05/24/99
File Version: 1.00
Compiler: Hi-Tech PIC C Compiler V7.83 PL3
Author: Richard L. Fischer
Company: Microchip Technology Incorporated

Files required:
- pic.h (Hi-Tech file)
- cnfig50x.h
- sensor08.c (Sensor Module code)
- powerup08.as (Hi-Tech file, modified)
- delay12.as (Delay Routine code)

Notes:
- PICmicro -> PIC12C508A
- Fosc -> Internal RC
- Weak-pull-ups disabled (current constraints)
- Wakeup from sleep --> typical 400ms
- Wake-up from sleep until test of GPWUF --> typical 20.03ms
- Current consumption in sleep mode: (sleep duration -> ~100sec)
  -> ~3.2mA @ 6.4Vdc (new battery)
  -> ~2.0mA @ 3.3Vdc (battery EOL)
- Sensor operational lower-limit voltage:
  -> 4Vdc (Low voltage status to base)
- Current consumption during wakeup:
  Housekeeping only: (typical 56mS)
  -> ~0.70mA @ 6.4Vdc
  -> ~0.30mA @ 3.3Vdc
  Intentional radiation: (typical 700mS)
  -> ~4.64mA @ 6.4Vdc
  -> ~2.22mA @ 3.3Vdc
- Memory Usage Map:
  - User segment $0000 - $0002 $0003 ( 3) bytes total User segment
  - Program ROM $0000 - $01FF $01FF ( 511) words
  - Program ROM $0200 - $02FF $0201 ( 512) words total Program ROM
  - Bank 0 RAM $0007 - $000C $0006 ( 6) bytes total Bank 0 RAM

Wireless Home Security with Keeloq and the PICmicro

Filename: delay12.as
Date: 07/18/99
File Version: 1.00

Notes:
The file contains the assembly code for executing intervals of a 1mS delay. The timing is based upon the PIC12C508A internal RC oscillator of 4MHz.

Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable".
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.
