

Sensor Interface

Sump Pump Controller

Author: Brian lehl Hoffman Estates, IL Email:brian@dls.net

PROBLEM

Most older sump pumps have a single level float control to regulate when the pump is turned on and off. When the water level rises to the float control, the pump turns on. The pump quickly pumps the water down to just below the float control in about a minute, shutting off the pump. Since the water level is just below the float control, the water rises enough to turn the sump pump on in just a couple of minutes. This control system makes the sump pump turn on 20 to 30 times an hour during a rain storm. This constant turning on and off of the motor leads to premature motor failure resulting in a flooded basement.

SOLUTION

Newer sump pumps have a two level control system. This project is intended to retrofit sump pumps that are already installed. The solution presented here uses a two water level control system. Using two water level sensors and the PIC12C508 microcontroller, we are able to introduce hysterisis into the control loop. This allows the pump to stay on longer and stay off longer during a rain storm. This reduction in power cycling leads to prolonged motor life, reducing the chance of having a failed sump pump lead to a flooded basement. The pump turns on when the water level reaches the top water level sensor and stays on until enough water is pumped out to lower the level to below the bottom sensor. The bottom sensor is positioned just above the lowest level the pump can operate at, so that the pump never dry pumps. The pump does not turn back on until the water level rises to the top sensor. This circuit is very cost effective allowing the consumer to retrofit an older sump pump instead of buying a new model.

APPLICATION OPERATION

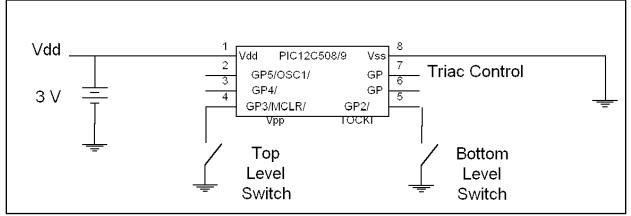

Two water level sensors are used. One sensing the desired top water level and the other sensing the desired bottom water level. The bottom water level sensor is used to ensure that the sump is never pumped completely dry, which could damage the sump pump. The PIC12C508 uses reads both sensor states and acts upon them according to the following table.

Тор:	On	Off	On	Off
Bottom:	On	On	Off	Off
Action:	Turn On	No Change	Invalid	Turn Off

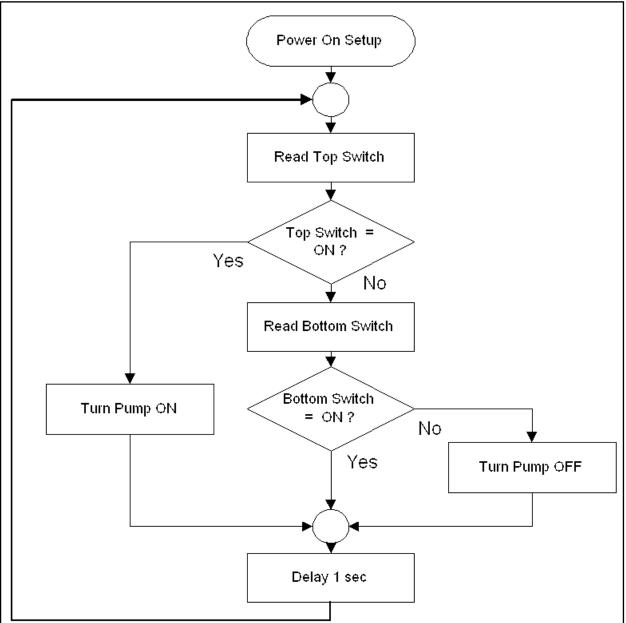

The condition that the bottom sensor is off and the top sensor is an invalid state. For this condition the pump is turned on as a fail safe measure. In case the bottom switch failed and was always reading off, this fail safe measure would still prevent sump from overflowing though functionality will be diminished to the standard type sump pump control.
