Section 8. Reset

HIGHLIGHTS

This section of the manual contains the following major topics:

8.1 Introduction ................................................................................................................ 8-2
8.2 Control Registers ........................................................................................................ 8-3
8.3 System Reset ............................................................................................................. 8-6
8.4 Using the RCON Status Bits ...................................................................................... 8-11
8.5 Device Start-Up Time Lines ...................................................................................... 8-12
8.6 Special Function Register Reset States ..................................................................... 8-14
8.7 Register Maps .......................................................................................................... 8-15
8.8 Design Tips .............................................................................................................. 8-16
8.9 Related Application Notes ......................................................................................... 8-17
8.10 Revision History ...................................................................................................... 8-18
8.1 INTRODUCTION

The Reset module combines all reset sources, and controls the device Master Reset Signal, SYSRST. The following is a list of device Reset sources:

- Power-on Reset (POR)
- Brown-out Reset (BOR)
- Master Clear Pin Reset (MCLR)
- RESET Instruction (SWR)
- Watchdog Time-out Reset (WDTO)
- Configuration Mismatch (CM) Reset – This reset source is not available on all devices. Refer to the specific device data sheet for more details.
- Trap Conflict Reset (TRAPR)
- Illegal Condition Device Reset (IOPUWR)
  - Illegal Opcode Reset
  - Uninitialized W Register Reset
  - Security Reset

Figure 8-1 shows a simplified block diagram of the Reset module. Any active source of reset will make the SYSRST signal active. On system Reset, some of the registers associated with the CPU and peripherals are forced to a known Reset state, while some are unaffected.

![Reset System Block Diagram](image)

**Note:** Refer to the specific peripheral section or refer to Section 2, “CPU” (DS70245) in the “PIC24H Family Reference Manual” for more details on the register Reset states.

**Note 1:** The configuration mismatch is not available on all the devices. Refer to the specific device data sheet for more details.
8.2 CONTROL REGISTERS

All types of device Reset, set a corresponding status bit in the RCON register to indicate the type of reset (see Register 8-1). A POR clears all bits except for the POR and BOR bits (RCON<1:0>), which are set. The user-assigned application can set or clear any bit at any time during code execution. The RCON bits only serve as status bits. Setting a particular Reset status bit in software will not cause a device Reset.

Register 8-1: RCON: Reset Control Register

<table>
<thead>

<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>CM(3)</td>
<td>VREGS</td>
</tr>
</tbody>
</table>

Legend:
R = Readable bit  
W = Writable bit  
U = Unimplemented bit, read as ‘0’  
-n = Value at POR  
‘1’ = Bit is set  
‘0’ = Bit is cleared  
x = Bit is unknown

bit 15  TRAPR: Trap Reset Flag bit  
1 = Trap Conflict Reset has occurred  
0 = Trap Conflict Reset has not occurred

bit 14  IOPUWR: Illegal Opcode or Uninitialized W Access Reset Flag bit  
1 = An illegal opcode detection, an illegal address mode or an uninitialized W register used as an Address Pointer caused a Reset  
0 = An illegal opcode or uninitialized W register Reset has not occurred

bit 13-10  Unimplemented: Read as ‘0’

bit 9  CM: Configuration Mismatch Flag bit(3)  
1 = Configuration mismatch Reset has occurred  
0 = Configuration mismatch Reset has not occurred

bit 8  VREGS: Voltage Regulator Standby During Sleep bit  
1 = Voltage regulator is active during Sleep  
0 = Voltage regulator goes into Standby mode during Sleep

bit 7  EXTR: External Reset (MCLR) Pin bit  
1 = Master Clear (pin) Reset has occurred  
0 = Master Clear (pin) Reset has not occurred

bit 6  SWR: Software Reset (Instruction) Flag bit  
1 = RESET instruction has executed  
0 = RESET instruction has not executed

bit 5  SWDTEN: Software Enable/Disable of WDT bit(2)  
1 = WDT is enabled  
0 = WDT is not enabled

bit 4  WDTO: Watchdog Time-out Flag bit  
1 = WDT time-out has occurred  
0 = WDT time-out has not occurred

bit 3  SLEEP: Wake-up from Sleep Flag bit  
1 = Device was in Sleep mode  
0 = Device was not in Sleep mode

Note 1: All of the Reset status bits can be set or cleared in software. Setting one of these bits in software does not cause a device Reset.

2: If the FWDTEN Configuration bit is ‘1’ (unprogrammed), the WDT is always enabled, regardless of the SWDTEN bit setting.

3: The configuration mismatch reset flag is not available on all the devices. Refer to the specific device data sheet for more details.
Register 8-1: RCON: Reset Control Register (Continued)(1)

bit 2  IDLE: Wake-up from Idle Flag bit
       1 = Device was in Idle mode
       0 = Device was not in Idle mode

bit 1  BOR: Brown-out Reset Flag bit
       1 = Brown-out Reset has occurred
       0 = Brown-out Reset has not occurred

bit 0  POR: Power-on Reset Flag bit
       1 = Power-on Reset has occurred
       0 = Power-on Reset has not occurred

Note 1: All of the Reset status bits can be set or cleared in software. Setting one of these bits in software does not cause a device Reset.

2: If the FWDTEN Configuration bit is ‘1’ (unprogrammed), the WDT is always enabled, regardless of the SWDTEN bit setting.

3: The configuration mismatch reset flag is not available on all the devices. Refer to the specific device data sheet for more details.
8.3 SYSTEM RESET

The PIC24H family of devices consists of two types of Reset:

- **Cold Reset**
- **Warm Reset**

A cold Reset is the result of a POR or BOR. On a cold Reset, FNOSC configuration bits in the FOSC device configuration register select the device clock source.

A warm Reset is the result of all other reset sources, including the `reset` instruction. On warm Reset, the device will continue to operate from the current clock source as indicated by the Current Oscillator Selection (COSC<2:0>) bits in the Oscillator Control (OSCCON<14:12>) register.

The device is kept in a Reset state until the system power supplies have stabilized at appropriate levels and the oscillator clock is ready. Figure 8-2 shows the sequence in which this occurs, and is detailed as follows:

1. **POR:** A POR circuit holds the device in Reset when the power supply is turned On. The POR circuit is active until VDD crosses the V_{POR} threshold and the delay T_{POR} has elapsed.

2. **BOR:** The on-chip voltage regulator has a BOR circuit that keeps the device in Reset until VDD crosses the V_{BOR} threshold and the delay T_{BOR} has elapsed. The delay T_{BOR} ensures the voltage regulator output becomes stable.

3. **PWRT Timer:** The programmable power-up timer continues to hold the processor in Reset for a specific period of time (T_{PWRT}) after a BOR. The delay T_{PWRT} ensures that the system power supplies have stabilized at the appropriate level for full-speed operation. After the delay T_{PWRT} has elapsed, the SYSRST becomes inactive, which in turn enables the selected oscillator to start generating clock cycles.

4. **Oscillator Delay:** The total delay for the clock to be ready for various clock source selections are provided in Table 8-1. Refer to Section 7. “Oscillator” (DS70227) in the “PIC24H Family Reference Manual” for more details.

5. When the oscillator clock is ready, the processor begins execution from location 0x000000. The user-assigned application programs a `GOTO` instruction at the reset address, which redirects program execution to the appropriate start-up routine.

6. The Fail-Safe Clock Monitor (FSCM), if enabled, begins to monitor the system clock when the system clock is ready and the delay T_{FSCM} elapsed.

### Table 8-1: Oscillator Delay

</tr>
</tbody>
</table>

**Note 1:** TOSCD = Oscillator Start-up Delay (1.1 μs max for FRC, 70 μs max for LPRC). Crystal Oscillator start-up times vary with Crystal characteristics, load capacitance, etc.

**Note 2:** TOST = Oscillator Start-up Timer Delay (1024 oscillator clock period). For example, TOST = 102.4 μs for a 10 MHz crystal and TOST = 32 ms for a 32 kHz crystal.

**Note 3:** TLOCK = PLL lock time (1.5 ms nominal), if PLL is enabled.
Figure 8-2: System Reset Timing

Note 1: POR: A POR circuit holds the device in Reset when the power supply is turned on. The POR circuit is active until VDD crosses the VPOR threshold and the delay TPOR has elapsed.

2: BOR: The on-chip voltage regulator has a BOR circuit that keeps the device in Reset until VDD crosses the VBOR threshold and the delay TBOR has elapsed. The delay TBOR ensures the voltage regulator output becomes stable.

3: PWRT Timer: The programmable power-up timer continues to hold the processor in Reset for a specific period of time (TPWRT) after a BOR. The delay TPWRT ensures that the system power supplies have stabilized at the appropriate level for full-speed operation. After the delay TPWRT has elapsed, the SYSRST becomes inactive, which in turn enables the selected oscillator to start generating clock cycles.

4: Oscillator Delay: The total delay for the clock to be ready for various clock source selections are provided in Table 8-1. Refer to Section 7. “Oscillator” (DS70227) in the “PIC24H Family Reference Manual” for more details.

5: When the oscillator clock is ready, the processor begins execution from location 0x000000. The user-assigned application programs a GOTO instruction at the reset address, which redirects program execution to the appropriate start-up routine.

6: The Fail-Safe Clock Monitor (FSCM), if enabled, begins to monitor the system clock when the system clock is ready and the delay TFSCM has elapsed.

Note: When the device exits the Reset condition (begins normal operation), the device operating parameters (voltage, frequency, temperature, etc.) must be within their operating ranges, otherwise the device may not function correctly. The user-assigned application must ensure that the delay between the time power is first applied and the time when the SYSRST becomes inactive is long enough to get all operating parameters within specification.
8.3.1 Power-on Reset (POR)
A POR circuit ensures the device is reset from power-on. The POR circuit is active until VDD crosses the VPOR threshold and the delay TPOR has elapsed. The delay TPOR ensures the internal device bias circuits become stable.

The device supply voltage characteristics must meet the specified starting voltage and rise rate requirements to generate the POR. Refer to the "Electrical Characteristics" section in the specific device data sheet for more details. The POR status (POR) bit in the Reset Control (RCON<0>) register is set to indicate the POR.

8.3.2 Brown-out Reset (BOR) and Power-up Timer (PWRT)
The on-chip regulator has a BOR circuit that resets the device when the VDD is too low (VDD<VBOR) for proper device operation. The BOR circuit keeps the device in Reset until VDD crosses VBOR threshold and the delay TBOR has elapsed. The delay TBOR ensures the voltage regulator output becomes stable.

The BOR status (BOR) bit in the Reset Control (RCON<1>) register is set to indicate the BOR. The device will not run at full speed after a BOR, as the VDD must rise to acceptable levels for full-speed operation. The PWRT provides power-up timer delay (TPWRT) to ensure that the system power supplies have stabilized at the appropriate levels for full-speed operation before the SYSRST is released.

The power-up timer delay (TPWRT) is programmed by the POR Timer Value Select (FPWRT<2:0>) bits in the POR Configuration (FPOR<2:0>) register, which provides eight settings (from 0 ms to 128 ms). Refer to Section 25. “Device Configuration” (DS70231) in the “PIC24H Family Reference Manual” for more details.

Figure 8-3 shows the typical brown-out scenarios. The reset delay (TBOR + TPWRT) is initiated each time VDD rises above the VBOR trip point.

Figure 8-3: Brown-out Scenarios

```
+-----------------+-----------------+-----------------+
| VDD             |               | VBOR            |

|                 | TBOR + TPWRT    |                 |
+-----------------+-----------------+-----------------+
```
8.3.3 External Reset (EXTR)

The EXTR Reset is generated by driving the MCLR pin low. The MCLR pin is a Schmitt Trigger input with an additional glitch filter. Reset pulses that are longer than the minimum pulse-width generate a Reset. Refer to the “Electrical Characteristics” section in the specific device data sheet for minimum pulse-width specifications. The External Reset (MCLR) Pin (EXTR) bit in the Reset Control (RCON) register is set to indicate the MCLR Reset.

8.3.3.1 EXTERNAL SUPERVISORY CIRCUIT

Many systems have external supervisory circuits that generate Reset signals to Reset multiple devices in the system. This external reset signal can be directly connected to the MCLR pin to Reset the device when the rest of system is Reset.

8.3.3.2 INTERNAL SUPERVISORY CIRCUIT

When using the internal power supervisory circuit to Reset the device, the external reset pin (MCLR) should be tied directly or resistively to VDD. In this case, the MCLR pin is not used to generate a Reset. The external reset pin (MCLR) does not have an internal pull-up and must not be left unconnected.

8.3.4 Software Reset Instruction (SWR)

Whenever the \textsc{reset} instruction is executed, the device will assert SYSRST, placing the device in a special Reset state. This reset state will not re-initialize the clock. The clock source in effect prior to the \textsc{reset} instruction remains. SYSRST is released at the next instruction cycle, and the reset vector fetch commences.

The Software Reset (Instruction) Flag (SWR) bit in the Reset Control (RCON<6>) register is set to indicate the Software Reset.

8.3.5 Watchdog Time-out Reset (WDTO)

Whenever a Watchdog Time-out occurs, the device will asynchronously assert SYSRST. The clock source remains unchanged. A WDT time-out during Sleep mode or Idle mode will wake-up the processor, but will not reset the processor.

8.3.6 Trap Conflict Reset

If a lower-priority hard trap occurs while a higher-priority trap is being processed, a hard trap conflict Reset occurs. The hard traps include exceptions of priority level 13 through level 15, inclusive. The address error (level 13) and oscillator error (level 14) traps fall into this category.

The Trap Reset Flag (TRAPR) bit in the Reset Control (RCON<15>) register is set to indicate the Trap Conflict Reset. Refer to Section 6. “Interrupts” (DS70224) in the “PIC24H Family Reference Manual” for more details on Trap Conflict Reset.

8.3.7 Configuration Mismatch Reset

To maintain the integrity of the peripheral pin select control registers, they are constantly monitored with shadow registers in hardware. If an unexpected change occurs in any of the registers (such as cell disturbances caused by ESD or other external events), a configuration mismatch Reset occurs.

The Configuration Mismatch Flag (CM) bit in the Reset Control (RCON<9>) register is set to indicate the configuration mismatch Reset. Refer to Section 30. “I/O Ports with Peripheral Pin Select” (DS70234) in the “PIC24H Family Reference Manual” for more details on the Configuration Mismatch Reset.

\textbf{Note:} The Configuration Mismatch feature and the associated reset flag is not available on all devices. Refer to the specific device data sheet for more details.
8.3.8 Illegal Condition Device Reset

An illegal condition device Reset occurs due to the following sources:

- Illegal Opcode Reset
- Uninitialized W Register Reset
- Security Reset

The Illegal Opcode or Uninitialized W Access Reset Flag (IOPUWR) bit in the Reset Control (RCON<14>) register is set to indicate the illegal condition device Reset.

8.3.8.1 Illegal Opcode Reset

A device Reset is generated, if the device attempts to execute an illegal opcode value that is fetched from program memory.

The illegal opcode Reset function can prevent the device from executing program memory sections that are used to store constant data. To take advantage of the illegal opcode Reset, use only the lower 16 bits of each program memory section to store the data values. The upper eight bits should be programmed with 0x3F, which is an illegal opcode value.

8.3.8.2 Uninitialized W Register Reset

Any attempts to use the uninitialized W register as an address pointer will Reset the device. The W register array (with the exception of W15) is cleared during all resets and is considered uninitialized until written to.

8.3.8.3 Security Reset

If a Program Flow Change (PFC) or Vector Flow Change (VFC) targets a restricted location in a protected segment (Boot and Secure Segment), that operation will cause a security Reset.

The PFC occurs when the Program Counter (PC) is reloaded as a result of a Call, Jump, Computed Jump, Return, Return from Subroutine, or other form of branch instruction.

The VFC occurs when the PC is reloaded with an Interrupt or Trap vector. Refer to Section 23. “CodeGuard™ Security” (DS70239) in the “PIC24H Family Reference Manual” for more details on Security Reset.
8.4 USING THE RCON STATUS BITS

The user-assigned application can read the Reset Control (RCON) register after any device Reset to determine the cause of the reset.

**Note:** The status bits in the RCON register should be cleared after they are read so that the next RCON register value after a device Reset is meaningful.

Table 8-2 provides a summary of the Reset flag bit operation.

<table>
<thead>
<tr>
<th>Flag Bit</th>

**Note:** All of the Reset flag bits can be set or cleared by the user software.
8.5 DEVICE START-UP TIME LINES

Figure 8-4 shows the device start-up time line when a crystal oscillator is used as the system clock. The power-up timer (PWRT) keeps the device in the Reset state for user-assigned application selected power-up timer delay (TPWRT) after a BOR to ensure that VDD rises to an acceptable level.

The crystal oscillator is enabled after SYSRST is released. Once enabled, the crystal oscillator takes a finite amount of time to start oscillating. This delay is denoted as TOSCD.

To ensure that a crystal oscillator (or ceramic resonator) has started and stabilized, a simple 10-bit counter counts 1024 oscillator clock cycles before releasing the oscillator clock. This time period is denoted as TOST. For example, TOST is 102.4μs for a 10 MHz crystal.

If the primary oscillator is used with the PLL, an additional delay is required for PLL locking. The device begins to execute after the clock is ready.

The Fail-Safe Clock Monitor (FSCM), if enabled, begins to monitor the system clock for activity when the system clock is ready and the delay TFSCM has elapsed.

Figure 8-4: Device Start-up Timing for Crystal Oscillator

Note 1: Delay times shown are not drawn to scale.
2: FSCM, if enabled, monitors system clock at expiration of TFSCM delay after device starts running.
3: TLOCK not inserted when PLL is disabled.
4: TPWRT is not inserted when PWRT delay is not enabled.
Figure 8-5 shows the device start-up time line when the FRC oscillator is used as the system clock. The FRC oscillator exhibits quick start-up delay (TOSCD) and the oscillator start-up time (TOST) is not required.

**Figure 8-5: Device Start-up Timing for FRC Oscillator**

Note 1: Delay times shown are not drawn to scale.
2: FSCM, if enabled, monitors system clock at expiration of TFSCM delay after device starts running.
3: TLOCK not inserted when PLL is disabled.
4: TPWRT is not inserted when PWRT delay is not enabled.
5: TOSCD for FRC is 1.1 µs.
8.6  SPECIAL FUNCTION REGISTER RESET STATES

Most of the special function registers (SFRs) associated with the PIC24H CPU and peripherals are reset to a particular value at a device Reset. The SFRs are grouped by their peripheral or CPU function and their Reset values are specified in the appropriate sections of this manual.

The Reset value for each SFR does not depend on the type of Reset, with the exception of two registers. The Reset value for the Reset Control register, RCON, depends on the type of device Reset. The Reset value for the Oscillator Control register, OSCCON, depends on the type of reset and the programmed values of the oscillator configuration bits in the FOSC Device Configuration register.
### 8.7 REGISTER MAPS

8.8 DESIGN TIPS

Question 1: How do I use the RCON register?

Answer: The initialization code after a device Reset should examine the RCON register and confirm the source of the reset. In certain applications, this information can be used to take appropriate action to correct the problem that caused the Reset to occur. All Reset status bits in the RCON register should be cleared after reading them to ensure the RCON value will provide meaningful results after the next device Reset.

Question 2: The BOR module does not have the programmable trip points that my application needs. How can I work around this?

Answer: The BOR circuitry is used to avoid the violation of V/F specification of the device. In many devices, the minimum voltage for full-speed operation is much higher. Therefore, a programmable BOR circuit is needed to provide the multiple speed option. The PIC24H devices support full-speed operation at a much lower voltage and the simple BOR module is enough. If the device operating voltage drops to a value where full-speed operation is not possible, then BOR is asserted. If the device is in a non-BOR state, then full-speed operation is valid.

Question 3: I initialized a W register with a 16-bit address, but the device appears to reset when I attempt to use the register as an address.

Answer: Because all data addresses are 16-bit values, the uninitialized W register logic only recognizes that a register has been initialized correctly if it was subjected to a word load. Two byte moves to a W register, even if successive, will not work, resulting in a device Reset if the W register is used as an address pointer in an operation.
8.9 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the PIC24H product family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the Reset module are:

<table>
<thead>
<tr>
<th>Title</th>
<th>Application Note #</th>

</tbody>
</table>

**Note:** For additional Application Notes and code examples for the PIC24H family of devices, visit the Microchip web site (www.microchip.com).
8.10 REVISION HISTORY

Revision A (February 2007)
This is the initial released revision of this document.

Revision B (May 2007)
Minor updates were made to this document.

Revision C (July 2009)
This revision includes the following updates:
• Sections:
  - Added Control Registers as a new section (see 8.2 “Control Registers”).
  - Added Register Maps as a new section (see 8.7 “Register Maps”).
• Tables:
  - Removed Table 8-2: Reset Characteristics, in 8.3 “System Reset”.
  - Added Reset Control Register Map (see Table 8-3) in 8.7 “Register Maps”.
• Additional minor corrections such as language and formatting updates are incorporated throughout the document.
