Section 15. Quadrature Encoder Interface (QEI)

HIGHLIGHTS

This section of the manual contains the following major topics:

15.1 Introduction ................................................................. 15-2
15.2 Control and Status Registers ........................................... 15-5
15.3 Module Description .................................................... 15-21
15.4 QEI Operation in Power-Saving Modes ....................... 15-29
15.5 Effects of a Reset ......................................................... 15-29
15.6 Register Map .............................................................. 15-30
15.7 Design Tips ................................................................. 15-31
15.8 Related Application Notes ............................................ 15-32
15.9 Revision History .......................................................... 15-33
15.1 INTRODUCTION

The Quadrature Encoder Interface (QEI) module provides the interface to incremental encoders for obtaining mechanical position data. Quadrature encoders, also known as incremental encoders or optical encoders, detect position and speed of rotating motion systems. Quadrature encoders enable closed-loop control of motor control applications, such as Switched Reluctance (SR) and AC Induction Motors (ACIM).

A typical quadrature encoder includes a slotted wheel attached to the shaft of the motor and an Emitter/Detector module that senses the slots in the wheel. Typically, three output channels, Phase A (QEA), Phase B (QEB) and Index (INDX) provide information on the movement of the motor shaft, including distance and direction.

The two channels, Phase A (QEA) and Phase B (QEB), are typically 90° out of phase with respect to each other. The Phase A and Phase B channels have a unique relationship. If Phase A leads Phase B, the direction of the motor is deemed positive or forward. If Phase A lags Phase B, the direction of the motor is deemed negative or reverse. The Index pulse occurs once per mechanical revolution and is used as a reference to indicate an absolute position. Figure 15-1 illustrates the quadrature encoder interface signals.

The quadrature signals from the encoder can have four unique states (01, 00, 10 and 11) that reflect the relationship between QEA and QEB. Figure 15-1 illustrates these states for one count cycle. The order of the states get reversed when the direction of travel changes.

The quadrature decoder increments or decrements the 32-bit Up/Down Position Counter (POSCNT) for each change of state. The counter increments when QEA leads QEB and decrements when QEB leads QEA.

Figure 15-1: Quadrature Encoder Interface Signals

Table 15-1 shows the truth table that describes how the quadrature signals are decoded.
Figure 15-2 illustrates the simplified block diagram of the QEI module. The QEI module consists of decoder logic to interpret the Phase A (QEA) and Phase B (QEB) signals, and an up/down counter to accumulate the count. The counter pulses are generated when the quadrature state changes. The count direction information must be maintained in a register until a direction change is detected. The module also includes digital noise filters, which condition the input signal.

The QEI module consists of the following major features:

- Four input pins: two phase signals, an index pulse and a home pulse
- Programmable digital noise filters on inputs
- Quadrature decoder providing counter pulses and count direction
- Count direction status
- x4 count resolution
- Index (INDX) pulse to reset the position counter
- General purpose 32-bit Timer/Counter mode
- Interrupts generated by QEI or counter events
- 16-bit velocity counter
- 32-bit position counter
- 32-bit index pulse counter
- 32-bit interval timer
- 32-bit position Initialization/Capture/Compare High Word register
- 32-bit position Initialization/Capture/Compare Low Word register
- 4X Quadrature Count mode
- External Up/Down Count mode
- External Gated Count mode
- External Gated Timer mode
- Interval Timer mode

Note 1: These registers map to the same memory location.
15.2 CONTROL AND STATUS REGISTERS

The following registers are associated with the QEI module:

- **QEIXCON**: QEI Control Register
  This register controls the QEI module operation.

- **QEIXIOC**: QEI I/O Control Register
  This register controls the input/output mode of the QEI module.

- **QEIXSTAT**: QEI Status Register
  This register provides the interrupt enable flag and status flag to indicate the status of the QEI module.

- **POSxCNTH**: Position Counter High Word Register
  This register is the high word of the position counter.

- **POSxCNTL**: Position Counter Low Word Register
  This register is the low word of the position counter.

- **POSxHLD**: Position Counter Hold Register
  This register holds the contents of the POSxCNTH register during the read or write operation.

- **VELxCNT**: Velocity Counter Register
  This register stores the velocity value.

- **INDXxCNTH**: Index Counter High Word Register
  This register is the high word of the index counter.

- **INDXxCNTL**: Index Counter Low Word Register
  This register is the low word of the index counter.

- **INDXxHLD**: Index Counter Hold Register
  This register holds the contents of the INDXxCNTH register during the read or write operation.

- **QEIXICH**: Initialization/Capture High Word Register
  This register is the high word of the QEIXIC register.

- **QEIXICL**: Initialization/Capture Low Word Register
  This register is the low word of the QEIXIC register.

- **QEIXLECH**: Less Than or Equal Compare High Word Register
  This register is the high word 16-bit less than or equal compare register.

- **QEIXLECL**: Less Than or Equal Compare Low Word Register
  This register is the low word 16-bit less than or equal compare register.

- **QEIXGECH**: Greater Than or Equal Compare High Word Register
  This register is the high word 16-bit greater than or equal compare register.

- **QEIXGECL**: Greater Than or Equal Compare Low Word Register
  This register is the low word 16-bit greater than or equal compare register.

- **INTxTMRH**: Interval Timer High Word Register
  This register is the high word of the Counter Pulse Interval Timer register.

- **INTxTMRL**: Interval Timer Low Word Register
  This register is the low word of the Counter Pulse Interval Timer register.

- **INTxHLDH**: Interval Timer Hold High Word Register
  This register holds the content of high word of the Interval Timer Hold register.

- **INTxHLDL**: Interval Timer Hold Low Word Register
  This register holds the content of low word of the Interval Timer Hold register.

Legend:
- R = Readable bit
- W = Writable bit
- U = Unimplemented bit, read as ‘0’
- -n = Value at POR ‘1’ = Bit is set ‘0’ = Bit is cleared x = Bit is unknown

**Note 1:** When CCM = 10 or CCM = 11, all of the QEI counters operate as timers and the PIMOD<2:0> bits are ignored.

**Note 2:** When CCM = 00 and QEA and QEB values match Index Match Value (IMV), the POSxCNTH and POSxCNTL registers are reset.

**Note 3:** The selected clock rate should be at least twice the expected maximum quadrature count rate.
Register 15-1:  QEIxCON: QEI Control Register (Continued)

bit 3  CNTPOL: Position and Index Counter/Timer Direction Select bit
       1 = Counter direction is negative unless modified by external Up/Down signal
       0 = Counter direction is positive unless modified by external Up/Down signal

bit 2  GATEN: External Count Gate Enable bit
       1 = External gate signal controls position counter operation
       0 = External gate signal does not affect position counter/timer operation

bit 1-0  CCM<1:0>: Counter Control Mode Selection bits
         11 = Internal Timer mode
         10 = External clock count with external Gate mode
         01 = External clock count with external Up/Down mode
         00 = Quadrature Encoder mode

Note 1:  When CCM = 10 or CCM = 11, all of the QEI counters operate as timers and the PIMOD<2:0> bits are ignored.

2:  When CCM = 00 and QEA and QEB values match Index Match Value (IMV), the POSxCNTH and POSxCNTL registers are reset.

3:  The selected clock rate should be at least twice the expected maximum quadrature count rate.
Register 15-2: QEIxIOC: QEI I/O Control Register

bit 15-0  INTHLD<15:0>: Low word used to form 32-bit Interval Timer Hold register (INTxHLD) bits
15.3 MODULE DESCRIPTION

15.3.1 Position Counter

The position counter is 32 bits wide and is contained in two separate 16-bit registers: POSxCNTL and POSxCNTH. The counter counts the number of pulses generated by an encoder.

To read the counter during the counter operation, the user application should first read the least significant word (lsw) of the counter value from the POSxCNTL register. When the lsw is read first, the contents of POSxCNTH are automatically transferred into a hold register, POSxHLD. The user application can then read the POSxHLD register to get the most significant word (msw) of the counter value. The hold register (POSxHLD) ensures that the occurrence of a carry or borrow between the read operation does not affect the reading of a coherent 32-bit value.

To write a value to the POSxCNTL:POSxCNTH register pair, the user application should first write the msw to the POSxHLD register. When the lsw of the timer value is written to the POSxCNTL register, the contents of POSxHLD are automatically transferred to the POSxCNTH register. Thus, a coherent 32-bit value can be loaded into the position counter in a single clock cycle.

If the POSOVIEN bit in the QEI Status register (QEIxSTAT<8>) is set, and the position counter rolls over from 0x7FFFFFFF to 0x80000000, or from 0x80000000 to 0x7FFFFFFF, an interrupt will be generated.

The operating mode of the position counter is controlled by the CCM<1:0> bits in the QEI Control register (QEIxCON<1:0>). The position counter supports the following operating modes:

- Quadrature Count Mode
- External Count with External Up/Down Mode
- External Count with External Gate Mode
- Internal Timer Mode

15.3.1.1 QUADRATURE COUNT MODE

In this mode, the QEA/EXTCNT and QEB/DIR/GATE inputs are decoded to generate count pulses and direction information to control the POSxCNT and VELxCNT. The INDXxCNT register counts when a valid edge is detected on INDX input. Figure 15-1 illustrates the timing diagram of the Quadrature Count mode operation.

15.3.1.2 EXTERNAL COUNT WITH EXTERNAL UP/DOWN MODE

In this mode, the QEA/EXTCNT input is considered as an external count signal, and the QEB/DIR/GATE input provides the count direction information. The count direction is positive unless overridden by the CNTPOL bit in the QEI Control register (QEIxCON<3>). Figure 15-3 illustrates the timing diagram of an External Count with External Up/Down mode operation.
15.3.1.3 EXTERNAL COUNT WITH EXTERNAL GATE MODE

In this mode, the QEA/EXTCNT input is considered as an external count signal. If the GATEN bit in the QEI Control register (QEIxCON<2>) is set, and QEB/DIR/GATE = 0, the QEB/DIR/GATE input will inhibit the counter signal. If the GATEN bit is cleared, the gate signal does not affect the counter operation. The default count direction is positive. If the CNTPOL bit in the QEI Control register (QEIxCON<3>) is set, the count direction is negative. Figure 15-4 illustrates the timing diagram of an External Count with External Gate mode operation.

![Figure 15-4: External Count with External Gate Mode](image)

15.3.1.4 INTERNAL TIMER MODE

In this mode, the velocity, index and interval center of the position counter uses an internal clock as the count source. The internal clock is divided by the clock divider using the INTDIV<2:0> bits in the QEI Control register (QEIxCON<6:4>). If the GATEN bit in the QEI Control register (QEIxCON<2>) is set, and QEB/DIR/GATE = 0, the QEB/DIR/GATE input will inhibit the counter signal. If the GATEN bit is cleared, the gate signal does not affect the operation of the counter. The default count direction is positive. If the CNTPOL bit in the QEI Control register (QEIxCON<3>) is set, the count direction is negative. Figure 15-5 illustrates the timing diagram of an Internal Timer mode operation.

**Note:** Although, the POSxCNT register allows byte accesses, reading from or writing to the POSxCNT register in Byte mode gives unpredictable results. As the hold register (POSxHLD) is only 16 bits wide, the operation in Byte mode is not recommended.

15.3.2 Velocity Counter

The Velocity Counter (VELxCNT) is a 16-bit wide register that increments or decrements based on the signal from the quadrature decoder logic. Reading this register results in a counter reset. The index input or any of the modes specified by the PIMOD<2:0> bits in the QEI Control register (QEIXCON<12:10>) does not affect the operation of the velocity counter. If the velocity counter rolls over from 0x7FFF to 0x8000, or from 0x8000 to 0x7FFF, and the VELOVIEN bit in the QEI Status register (QEIXSTAT<4>) is set, an interrupt will be generated. Figure 15-6 illustrates the timing diagram of the Velocity Counter operation.

**Note:** The velocity counter specifies the distance traveled between the time interval of each sample. Reading the VELxCNT register results in counter reset. The user application should read the velocity counter at a rate of 1-4 kHz.
15.3.3 Index Counter

The Index Counter (INDXxCNT) is 32 bits wide and is contained in two separate 16-bit registers: INDXxCNTH and INDXxCNTL. It counts the index events and is incremented or decremented based on the direction output of the quadrature logic decoder (see Figure 15-2). For more information, refer to 15.3.7 “Index Event”.

To read the index counter during the counter operation, the user application should first read the lsw of the counter value from the INDXxCNTL register. When the lsw is read first, the contents of the INDXxCNTH register are automatically transferred into a hold register, INDXxHLD. The user application can then read the INDXxHLD register to get the msw of the counter value.

To write a value to the INDXxCNTH:INDXxCNTL register pair, the user application should first write the msw to the INDXxHLD register. When the lsw of the index value is written to the INDXxCNTL register, the contents of the INDXxHLD register is automatically transferred to the INDXxCNTH register. Thus, a coherent 32-bit value can be loaded into the index counter in a single clock cycle.

Note: Although, the INDXxCNT register allows byte accesses, reading from or writing to the POSxCNT register in Byte mode gives unpredictable results. As the hold register (POSxHLD) is only 16 bits wide, the operation in Byte mode is not recommended.

15.3.4 Interval Timer

When a motor runs at a very low speed, the encoder does not generate enough pulses for accurate speed measurement. Therefore, instead of counting the number of pulses, the pulse duration can be measured. The 32-bit Interval Timer (INTxTMR) is used to measure the time interval between each decoded quadrature count pulse when the motor operates at a very low speed. The timer counts at a rate specified by the INTDIV<2:0> bits in the QEI Control register (QEIxCON<6:4>). The interval timer is cleared when the first count pulse is detected. When the next count pulse is detected, the current contents of the interval timer are transferred to the interval hold registers (INTxHLDH and INTxHLDL), the interval timer is cleared, and then the process repeats. The interval hold registers always contain the most recent completed timing measurements. Figure 15-7 illustrates the timing diagram of the Interval Timer operation.

Note: If the INTxHLD register is read when a new position count pulse is detected, the contents of the INTxHLD register are not updated to avoid incoherent data reading.
15.3.5 Initialization/Capture Register

The 32-bit Initialization/Capture register (QEixIC) is a general purpose register that can be used to perform the following functions:

- Initialize the position counter
- Capture the contents of the position counter

The QEixIC register can perform only one of these tasks at a time, but the mode of operation can be changed during the operation. The selection is done by the PIMOD<2:0> bits of the QEi Control register (QEixCON<12:10>). To initialize the Position Counter mode, the contents of QEixIC register are loaded into the POSxCNT register based on the condition set by the PIMOD<2:0> bits.

In Capture mode, the input signal is used to capture the contents of the position register into the QEixIC register. This register can be configured to define a travel boundary beyond which a fault is generated.

15.3.6 Position Comparator

The 32-bit Compare register and associated comparator allow the user application to compare the contents of the position counter to a specified value. The comparator provides two outputs: greater than or equal, and less than or equal. When a suitable condition is met, the comparator generates an interrupt by setting the PCHEQIRQ or PCLEQIRQ bit in the QEi Status register (QEixSTAT<13> and QEixSTAT<11>). The comparator output is available on the CNTCMPx pin. The selection of condition is made by the OUTFNC<1:0> bits of the QEi I/O Control register (QEixIOC<10:9>). The comparator can also be used to reset the position counter when a match is detected. The selection is made by the PIMOD<2:0> bits of the QEi Control register (QEixCON<12:10>). Figure 15-8 illustrates the index reset position counter operation.
15.3.7 Index Event

The IMV<1:0> bits in the QEI Control register (QEIxCON<9:8>) specify the state of the QEA and QEB input signals required to acknowledge an index event. An index event is accepted when an index pulse occurs while the value of the QEA and QEB inputs match the condition set in the IMV<1:0> bits. This prevents further index events from being accepted until the index input signal is deasserted, and ensures that only one index event occurs for each index input pulse. Figure 15-8 illustrates the index reset position counter operation.
15.3.8 Position Counter Initialization Modes

By using the PIMOD<2:0> bits in the QEI Control register (QEIXCON<12:10>), the user application can specify how the position counter is initialized during the module operation.

- **Mode 0** - The position counter is unaffected by the index input.
- **Mode 1** - The position counter is cleared whenever an index input event is detected.
- **Mode 2** - The position counter is initialized with the contents of the QEIxIC register on the next detected index input event. When the index event occurs, the PIMOD<2:0> bits are cleared, and then the counter operates in Mode 0.
- **Mode 3** - The position counter is initialized with the contents of the QEIxIC register on the next detected index input event following the assertion of the home input. When an index event occurs following the home event, the PIMOD<2:0> bits are cleared, and then the counter operates in Mode 0.
- **Mode 4** - The position counter is initialized with the contents of the QEIxIC register on the second detected index input event following the assertion of the home input. When the second index event occurs following the home event, the PIMOD<2:0> bits are cleared, and then the counter operates in Mode 0.
- **Mode 5** - The position counter is cleared when the position counter value equals the QEIxIC register value.
- **Mode 6** - The position counter is loaded with the contents of the QEIxLEC register when the position counter value equals the QEIxGEC register value and a count up pulse is detected. The counter is loaded with the contents of the QEIxGEC register when the position counter value equals the QEIxLEC register value and a count down pulse is detected.
- **Mode 7** - Reserved; the position counter selects the default Mode 0 operation.

15.3.9 Digital Input Filter

The QEI module uses digital noise filters to reject noise on the incoming index and quadrature phase signals. These filters reject low-level noise and large, short duration noise spikes that typically occur in motor systems.

The filtered output signals can change only after an input level has the same value for three consecutive rising clock edges. The result is that short noise spikes between rising clock edges are ignored, and pulses shorter than two clock periods are rejected.

The filter clock rate determines the low passband of the filter. A slower filter clock results in a passband rejecting lower frequencies.

The digital filter is enabled by setting the FLTREN bit in the QEI I/O Control register (QEIxIOC<14>). The QFDIV<2:0> bits in the QEI I/O Control register (QEIxIOC<13:11>) select the filter clock divider ratio for the clock signal.

Figure 15-9 illustrates the simplified block diagram of the digital noise filter.

Figure 15-9: Block Diagram of Digital Noise Filter
15.3.10 Interrupts

The following are the sources of QEI interrupts:

- Position counter overflow or underflow event
- Velocity counter overflow or underflow event
- Position counter initialization process complete
- Position counter greater than or equal compare interrupt
- Position counter less than or equal compare interrupt
- Index event interrupt
- Home event interrupt

The QEI Status register (QEIxSTAT) contains the individual interrupt enable bits and the corresponding interrupt status bits for each interrupt source. A status bit indicates that an interrupt request has occurred. The module reduces all of the QEI interrupts to a single interrupt signal to the interrupt controller module.

15.4 QEI OPERATION IN POWER-SAVING MODES

15.4.1 Sleep Mode

When the device enters Sleep mode, QEI operations cease. The POSxCNT register stops at the current value. The QEI does not respond to active signals on the QEA, QEB or INDX pins. The QEIxCON register remains unchanged.

15.4.2 Idle Mode

When the device enters Idle mode, the QEISIDL bit in the QEI Control register (QEIxCON<13>) determines whether the QEI module stops in Idle mode or continues to operate in Idle mode.

If QEICSIDL = 1, the QEI module enters into a power-saving mode and performs the same functions as in Sleep mode. If QEICSIDL = 0, the module does not enter into a power-saving mode and continues operation in Idle mode.

15.4.3 Doze Mode

The QEI operation in Doze mode is similar as in normal mode.

15.5 EFFECTS OF A RESET

A Reset forces module registers to their initial Reset state.
15.6 REGISTER MAP

A summary of the registers associated with the dsPIC33E/PIC24E family's Quadrature Encoder Interface (QEI) module is provided in Table 15-2.

15.7 DESIGN TIPS

**Question 1: How do I configure the software when hardware signals are interchanged?**

**Answer:**
The HOMPOL, IDXPOL, QEBPOL and QEAPOL bits in the QEIxIOC register allow the user application to invert the polarity of their associated input signals. The SWPAB bit in the QEIxIOC, when set, swaps the QEA and QEB signals prior to their input into the quadrature decoder. Swapping of the signals reverses the direction of count. The OUTFNC<1:0> bits in the QEIxIOC register (QEIxIOC<10:9>) allow the user application to output the internal module state or the status of the position counter comparator on a device pin. The output timing is non-critical because the selected signal is used by the customer’s application circuit, which is external to the device.

**Question 2: How do I debug the software using the QEI module?**

**Answer:**
The QEIxIOC register can be used to configure the external inputs and outputs of the QEI module.

When setting up or troubleshooting a motion control-based application, the HOME, INDEX, QEB and QEA status bits in the QEIxIOC register can be used to monitor the individual state of their associated inputs.

A sensor or signal can be connected to the Home input by setting the QCAPEN bit in the QEI I/O Control register (QEIxIOC<15>). When set, it allows the user application to capture the current position counter value and save it in the QEIxIC register. If the filter is enabled, the Home event is detected when a rising edge of the filtered Home signal occurs. When a Home event occurs, an interrupt generation can be enabled by setting the HOMIEN bit in the QEI Status register (QEIxSTAT<2>).
15.8 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the dsPIC33E/PIC24E device family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the QEI module are:

<table>
<thead>
<tr>
<th>Title</th>
<th>Application Note #</th>
</tr>
</thead>
<tbody>
<tr>
<td>Servo Control of a DC-Brush Motor</td>
<td>AN532</td>
</tr>
<tr>
<td>PIC18CXXX/PIC16CXXX DC Servomotor Application</td>
<td>AN696</td>
</tr>
<tr>
<td>Using the dsPIC30F for Vector Control of an ACIM</td>
<td>AN908</td>
</tr>
</tbody>
</table>

**Note:** Please visit the Microchip web site (www.microchip.com) for additional application notes and code examples for the dsPIC33E/PIC24E family of devices.
Section 15. Quadrature Encoder Interface (QEI)

15.9 REVISION HISTORY

Revision A (June 2009)
This is the initial released version of this document.

Revision B (May 2010)
This version of the document includes the following updates:

- The document has been renamed from dsPIC33E Family Reference Manual to dsPIC33E/PIC24E Family Reference Manual
- Updated the QEIxCON: QEI Control Register (Register 15-1):
  - Renamed the register from QEICON to QEIxCON
  - Updated the PIMOD<12:10> = 111 definition
  - Changed the bit value definitions of CCM<1:0>
- Updated the QEIxIOC: QEI I/O Control Register (Register 15-2):
  - Renamed the register from QEIIOC to QEIxIOC
  - Updated the QCAPEN<15> = 0 definition
  - Changed the bit value definitions of OUTFNC<10:9>
  - Changed the bit value definitions of SWPAB<8>
  - Updated the bit name of QFDIV<13:11>, HOMPOL<7>, IDXPOL<6>, QEBPOL<5> and QEA<0>
- Updated the QEIxSTAT: QEI Status Register (Register 15-3):
  - Renamed the register from QEISTAT to QEIxSTAT
  - Updated the bit name and bit value definitions of PCHEQIEN<12>, PCLEQIEN<11>, PCIIRQ<7>, HOMIRQ<3> and IDXIRQ<1>
  - Updated the bit name of PCHEQIEN<12>, PCLEQIEN<10> and IDXIEN<0>
  - Changed the bit value definitions of POSOVIRQ<9> and VELOVIRQ<5>
  - Add Note 1 to PCIIRQ<7> bit
- Updated the POSxCNTH: Position Counter High Word Register (Register 15-4):
  - Renamed the register from POSCNTH to POSxCNTH
  - Changed the bit name of POSCNTH to POSCNT and updated the definition
- Updated the POSxCNTL: Position Counter Low Word Register (Register 15-5):
  - Renamed the register from POSCNTL to POSxCNTL
  - Changed the bit name of POSCNTL to POSCNT and updated the definition
- Updated the POSxHLD: Position Counter Hold Register (Register 15-6):
  - Renamed the register from POSHLDH to POSxHLD
  - Updated the bit definition of POSHLD<15:0>
- Updated the VELxCNT: Velocity Counter Register (Register 15-7):
  - Renamed the register from VELCNT to VELxCNT
  - Updated the bit name of VELCNT
- Updated the INDXxCNTH: Index Counter High Word Register (Register 15-8):
  - Renamed the register from IDXCNTH to INDXxCNTH
  - Changed the bit name of IDXCNTH to INDXCNT and updated the bit definition
- Updated the INDXxCNTL: Index Counter Low Word Register (Register 15-9):
  - Renamed the register from IDXCNTL to INDXxCNTL
  - Changed the bit name and updated the definition of INDXCNT<15:0>
  - Changed the bit name of IDXCNTL to INDXCNT and updated the bit definition
- Updated the INDXxHLD: Index Counter Hold Register (Register 15-10):
  - Renamed the register from IDXHLDH to INDXxHLD
  - Changed the bit name of IDXHLDH to INDXxHLD and updated the bit definition
Revision B (May 2010) (Continued)

- Updated the QEIXICH: Initialization/Capture High Word Register (Register 15-11):
  - Renamed the register from ICCH to QEIXICH
  - Changed the bit name of ICCH to QEIIC and updated the bit definition
- Updated the QEIXICL: Initialization/Capture Low Word Register (Register 15-12):
  - Renamed the register from ICCL to QEIXICL
  - Changed the bit name of ICCL to QEIIC and updated the bit definition
- Added the QEIXLECH: Less Than or Equal Compare High Word Register (Register 15-13)
- Added the QEIXLECL: Less Than or Equal Compare Low Word Register (Register 15-14)
- Added the QEIXGECH: Greater Than or Equal Compare High Word Register (Register 15-15)
- Added the QEIXGECL: Greater Than or Equal Compare Low Word Register (Register 15-16)
- Updated the INTxTMRH: Interval Timer High Word Register (Register 15-17):
  - Renamed the register from INTTMRH to INTxTMRH
  - Changed the bit name of INTTMRH to INTTMR
- Updated the INTxTMRL: Interval Timer Low Word Register (Register 15-18):
  - Renamed the register from INTTMRL to INTxTMRL
  - Changed the bit name of INTTMRL to INTTMR
- Updated the INTxHLDH: Interval Timer Hold High Word Register (Register 15-19):
  - Renamed the register from INTHLDH to INTxHLDH
  - Changed the bit name of INTHLDH to INTHLD
- Updated the INTxHLDDL: Interval Timer Hold Low Word Register (Register 15-20):
  - Renamed the register from INTHLDDL to INTxHLDDL
  - Changed the bit name of INTHLDDL to INTHLD
- Deleted the CMPLH: Compare Register High Word and CMPLL: Compare Register Low Word registers
- All new register names and acronyms are updated throughout the document
- Updated all the timing diagrams in the document
- Updated the content in 15.3.7 “Index Event”
- Updated the bulleted list in 15.3.10 “Interrupts”
- Deleted UPDN pin in 15.4.1 “Sleep Mode”
- Minor typographical and formatting corrections were made throughout the document
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Trademarks

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, dsPIC® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
