Section 53. Interrupts (Part VI)

HIGHLIGHTS

This section of the manual contains the following major topics:

53.1 Introduction ................................................................. 53-2
53.2 Non-Maskable Traps ...................................................... 53-8
53.3 Interrupt Processing Timing .......................................... 53-13
53.4 Interrupt Control and Status Registers ....................... 53-16
53.5 Interrupt Setup Procedures ......................................... 53-42
53.6 Register Map ............................................................... 53-45
53.7 Design Tips ................................................................. 53-46
53.8 Related Application Notes ............................................ 53-47
53.9 Revision History .......................................................... 53-48
53.1 INTRODUCTION

This section contains device-specific information for the following devices:

- dsPIC33FJ16GP101
- dsPIC33FJ16GP102
- dsPIC33FJ16MC101
- dsPIC33FJ16MC102

The dsPIC33F/PIC24H Interrupt Controller module reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the dsPIC33F/PIC24H CPU. The features of this module include the following:

- Up to eight processor exceptions and software traps
- Seven user-selectable priority levels
- Interrupt Vector Table (IVT) with up to 126 vectors
- Unique vector for each interrupt or exception source
- Fixed priority within a specified user priority level
- Alternate Interrupt Vector Table (AIVT) for debugging support
- Fixed interrupt entry and return latencies

53.1.1 Interrupt Vector Table

The Interrupt Vector Table (IVT) illustrated in Figure 53-1, resides in program memory starting at location 0x000004. The IVT contains 126 vectors that consist of eight non-maskable trap vectors and up to 118 sources of interrupt. In general, each interrupt source has its own vector. Each interrupt vector contains a 24 bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Route (ISR).

53.1.2 Alternate Interrupt Vector Table

The Alternate Interrupt Vector Table (AIVT) is located after the IVT, as shown in Figure 53-1. Access to the AIVT is provided by the Enable Alternate Interrupt Vector Table (ALTIVT) control bit in Interrupt Control Register 2 (INTCON2<15>). If the ALTIVT bit is set, all interrupt and exception processes use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging by providing a means to switch between an application and a support environment without reprogramming the interrupt vectors. This feature also enables switching between applications for evaluation of different software algorithms at run time. If the AIVT is not needed, the AIVT must be programmed with the same addresses used in IVT.

53.1.3 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The dsPIC33F/PIC24H device clears its registers during a Reset, that forces the Program Counter (PC) to zero. The processor then begins program execution at location 0x000000. The user application programs a GOTO instruction at the Reset address, that redirects program execution to the appropriate start-up routine.

Note: Any unimplemented or unused vector locations in the IVT and AIVT must be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

53.1.4 CPU Priority Status

The CPU can operate at one of 16 priority levels that range from 0-15. An interrupt or trap source must have a priority level greater than the current CPU priority to initiate an exception process. The peripheral and external interrupt sources for levels 0-7 can be programmed. CPU priority levels 8-15 are reserved for trap sources.

A trap is a non-maskable interrupt source intended to detect hardware and software problems (see 53.2 “Non-Maskable Traps”). The priority level for each trap source is fixed. Only one trap is assigned to a priority level. An interrupt source programmed to priority level 0 is disabled, because it can not be greater than the CPU priority.

The current CPU priority level is indicated by the following status bits:

- CPU Interrupt Priority Level (IPL<2:0>) status bits in the CPU Status Register (SR<7:5>)
- CPU Interrupt Priority Level 3 (IPL3) status bit in the Core Control (CORCON<3>) register

Because the IPL<2:0> status bits are readable and writable, the user-assigned application can modify these bits to disable all sources of interrupts below a given priority level. For example, if IPL<2:0> = 011, the CPU is not interrupted by any source with a programmed priority level of 0, 1, 2, or 3.

Trap events have higher priority than any user interrupt source. When the IPL3 bit is set, a trap event is in progress. The IPL3 bit can be cleared, but can not be set, by the user-assigned application. In some applications, you may need to clear the IPL3 bit when a trap has occurred and branch to an instruction other than the instruction after the one that originally caused the trap to occur.

All user interrupt sources can be disabled by setting IPL<2:0> = 111.

```
Note: The IPL<2:0> bits become read-only bits when interrupt nesting is disabled. For more information, see 53.2.4.2 “Interrupt Nesting”.
```

53.1.5 Interrupt Priority

Each peripheral interrupt source can be assigned to one of seven priority levels. The user application-assignable interrupt priority control bits for each individual interrupt are located in the Least Significant 3 bits of each nibble within the IPCx registers. Bit 3 of each nibble is not used and is read as a ‘0’. These bits define the priority level assigned to a particular interrupt. The usable priority levels are 1 (lowest priority) through 7 (highest priority). If the IPC bits associated with an interrupt source are all cleared, the interrupt source is effectively disabled.

```
Note: The application program must disable the interrupts while reconfiguring the interrupt priority levels on the fly. Failure to disable interrupts can produce unexpected results.
```

More than one interrupt request source can be assigned to a specific priority level. To resolve priority conflicts within a given user application-assigned level, each source of interrupt has a natural order priority based on its location in the IVT. Table 53-1 lists the location of each interrupt source in the IVT. The lower numbered interrupt vectors have higher natural priority, while the higher numbered vectors have lower natural priority. The overall priority level for any pending source of interrupt is first determined by the user application-assigned priority of that source in the IPCx register, and then by the natural order priority within the IVT.

Natural order priority is used only to resolve conflicts between simultaneous pending interrupts with the same user application-assigned priority level. After the priority conflict is resolved and the exception process begins, the CPU can be interrupted only by a source with a higher user application-assigned priority. Interrupts with the same user application-assigned priority but a higher natural order priority that become pending during the exception process remain pending until the current exception process completes.
Assigning each interrupt source to one of seven priority levels enables the user-assigned application to give an interrupt with a low natural order priority, a very high overall priority level. For example, Timer2 can be given a priority of 7 and the External Interrupt 0 (INT0) can be assigned to priority level 1, giving it a very low effective priority.

**Note:** The peripherals and sources of interrupt available in the IVT vary depending on the specific dsPIC33F/PIC24H device. The sources of interrupt shown in this document represent a comprehensive listing of all interrupt sources found on dsPIC33F/PIC24H devices. For more information, refer to the specific device data sheet.
53.2 NON-MASKABLE TRAPS

Traps are non-maskable, nestable interrupts that adhere to a fixed priority structure. Traps provide a means to correct erroneous operation during debugging and operation of the application. If the user-assigned application does not intend to correct a trap error condition, these vectors must be loaded with the address of a software routine to reset the device. Otherwise, the user-assigned application programs the trap vector with the address of a service routine that corrects the trap condition.

The dsPIC33F/PIC24H consists of four implemented sources of non-maskable traps:

• Oscillator Failure Trap
• Stack Error Trap
• Address Error Trap
• Math Error Trap

For many of the trap conditions, the instruction that caused the trap to complete before exception processing begins. Therefore, the user application may have to correct the action of the instruction that caused the trap.

Each trap source has a fixed priority as defined by its position in the IVT. An oscillator failure trap has the highest priority, while a math error trap has the lowest priority (see Figure 53-1). In addition, trap sources are classified into two distinct categories: “hard” traps and “soft” traps.

53.2.1 Soft Traps

The math error trap (priority level 11) and stack error trap (priority level 12) are categorized as soft trap sources. Soft traps can be treated like non-maskable sources of interrupt that adhere to the priority assigned by their position in the IVT. Soft traps are processed like interrupts and require two cycles to be sampled and acknowledged prior to exception processing. Therefore, additional instructions may be executed before a soft trap is acknowledged.

53.2.1.1 STACK ERROR TRAP (SOFT TRAP, LEVEL 12)

The stack is initialized to 0x0800 during a Reset. A stack error trap is generated, if the stack pointer address is less than 0x0800.

A Stack Limit (SPLIM) register associated with the stack pointer is uninitialized at Reset. The stack overflow check is not enabled until a word is written to the SPLIM register.

All Effective Addresses (EA) generated using W15 as a source or destination pointer are compared against the value in the SPLIM register. If the EA is greater than the contents of the SPLIM register, a stack error trap is generated. In addition, a stack error trap is generated if the EA calculation wraps over the end of data space (0xFFFF).

A stack error can be detected in software by polling the Stack Error Trap (STKERR) status bit (INTCON1<2>). To avoid re-entering the trap service routine, the STKERR status flag must be cleared in software with a RETFIE (Return from Interrupt) instruction before the program returns from the trap.

53.2.1.2 MATH ERROR TRAP (SOFT TRAP, LEVEL 11)

Any of the following events will generate a math error trap:

• Accumulator A overflow
• Accumulator B overflow
• Catastrophic accumulator overflow
• Divide by zero
• Shift Accumulator (SFTAC) operation that exceeds ±16 bits

The following three bits in the INTCON1 register enable the three types of accumulator overflow traps:

• The Accumulator A Overflow Trap Flag (OVATE) control bit (INTCON1<10>) enables traps for an Accumulator A overflow event.
• The Accumulator B Overflow Trap Flag (OVBTE) control bit (INTCON1<9>) enables traps for an Accumulator B overflow event.
• The Catastrophic Overflow Trap Enable (COVTE) control bit (INTCON1<8>) enables traps for a catastrophic overflow of either accumulator. When this trap is detected, these corresponding ERROR bits are set in the INTCON1 register:
  - Accumulator A Overflow Trap Flag (OVAERR)
  - Accumulator B Overflow Trap Flag (OVBERR)
  - Accumulator A Catastrophic Overflow Trap Enable (COVAERR)
  - Accumulator B Catastrophic Overflow Trap Enable (COVBERR)

An Accumulator A or Accumulator B overflow event is defined as a carry-out from bit 31. The accumulator overflow cannot occur, if the 31-bit Saturation mode is enabled for the accumulator. A catastrophic accumulator overflow is defined as a carry-out from bit 39 of either accumulator. The catastrophic overflow cannot occur, if accumulator saturation (31-bit or 39-bit) is enabled.

Divide-by-zero traps cannot be disabled. The divide-by-zero check is performed during the first iteration of the REPEAT loop that executes the divide instruction. The Math Error Status (DIV0ERR) bit (INTCON1<6>) is set when this trap is detected.

Accumulator shift traps cannot be disabled. The SFTAC instruction can be used to shift the accumulator by a literal value or a value in one of the W registers. If the shift value exceeds ±16 bits, an arithmetic trap is generated and the Shift Accumulator Error Status (SFTAERR) bit (INTCON1<7>) is set. The SFTAC instruction executes, but the results of the shift are not written to the target accumulator.

A math error trap can be detected in software by polling the Math Error Status (MATHERR) bit (INTCON1<4>). To avoid re-entering the trap service routine, the MATHERR status flag must be cleared in software with a RETFIE instruction before the program returns from the trap. Before the MATHERR status bit can be cleared, all conditions that caused the trap to occur must also be cleared. If the trap was due to an accumulator overflow, the Accumulator Overflow (OA and OB) status bits (SR<15:14>) must be cleared. The OA and OB status bits are read-only, so the user application must perform a dummy operation on the overflowed accumulator (like adding ‘0’), which causes the hardware to clear the OA or OB status bit.

### 53.2.2 Hard Traps

Hard traps include exceptions of priority level 13 through level 15, inclusive. The address error (level 13) and oscillator error (level 14) traps fall into this category.

Like soft traps, hard traps are non-maskable sources of interrupt. The difference between hard traps and soft traps is that hard traps force the CPU to stop code execution after the instruction causing the trap has completed. Normal program execution flow does not resume until the trap is acknowledged and processed.

#### 53.2.2.1 TRAP PRIORITY AND HARD TRAP CONFLICTS

If a higher-priority trap occurs while any lower-priority trap is in progress, processing of the lower-priority trap is suspended. The higher-priority trap is acknowledged and processed. The lower-priority trap remains pending until processing of the higher-priority trap completes.

Each hard trap that occurs must be acknowledged before code execution of any type can continue. If a lower-priority hard trap occurs while a higher-priority trap is pending, acknowledged or being processed, a hard-trap conflict occurs because the lower-priority trap cannot be acknowledged until processing for the higher-priority trap completes.

The device is automatically reset in a hard-trap conflict condition. The Trap Reset Flag (TRAPR) status bit in the Reset Control register (RCON<15> in the Reset module) is set when the Reset occurs so that the condition can be detected in software.

#### 53.2.2.2 OSCILLATOR FAILURE TRAP (HARD TRAP, LEVEL 14)

An oscillator failure trap event is generated for any of the following reasons:

- The Fail-Safe Clock Monitor (FSCM) is enabled and has detected a loss of the system clock source.
- A loss of PLL lock has been detected during normal operation using the PLL.
- The FSCM is enabled and the PLL fails to achieve lock at a Power-on Reset (POR).
An oscillator failure trap event can be detected in software by polling the Oscillator Failure Trap (OSCFAIL) status bit (INTCON1<1>) or the Clock Fail (CF) status bit (OSCCON<3>) in the Oscillator module. To avoid re-entering the Trap Service Routine (TSR), the OSCFAIL status flag must be cleared in software with a RETFIE instruction before the program returns from the trap.

53.2.2.3 ADDRESS ERROR TRAP (HARD TRAP, LEVEL 13)

Operating conditions that can generate an address error trap include the following:

- A misaligned data word fetch is attempted. This condition occurs when an instruction performs a word access with the Least Significant bit (LSb) of the effective address set to '1'. The dsPIC33F/PIC24H CPU requires all word accesses to be aligned to an even address boundary.
- A bit manipulation instruction uses the Indirect Addressing mode with the LSb of the effective address set to '1'.
- A data fetch is attempted from unimplemented data address space.
- Execution of a BRA #literal instruction or a GOTO #literal instruction, where literal is an unimplemented program memory address.
- Execution of instructions after the Program Counter has been modified to point to unimplemented program memory addresses. The Program Counter can be modified by loading a value into the stack and executing a RETURN instruction.

When an address error trap occurs, data space writes are inhibited so that data is not destroyed. An address error can be detected in software by polling the ADDRERR status bit (INTCON1<3>). To avoid re-entering the Trap Service Routine, the ADDRERR status flag must be cleared in software with a RETFIE instruction before the program returns from the trap.

53.2.3 Disable Interrupts Instruction

The DISI (disable interrupts) instruction can disable interrupts for up to 16384 instruction cycles. This instruction is useful for executing time-critical code segments. The DISI instruction only disables interrupts with priority levels 1-6. Priority level 7 interrupts and all trap events can still interrupt the CPU when the DISI instruction is active.

The DISI instruction works in conjunction with the Disable Interrupts Count (DISICNT) register in the CPU. When the DISICNT register is non-zero, priority level 1-6 interrupts are disabled. The DISICNT register is decremented on each subsequent instruction cycle. When the DISICNT register counts down to zero, priority level 1-6 interrupts are re-enabled. The value specified in the DISI instruction includes all cycles due to PSV accesses, instruction stalls and so on.

The DISICNT register is readable and writable. The user-assigned application can terminate the effect of a previous DISI instruction early by clearing the DISICNT register. The time that interrupts are disabled can be increased by writing to or adding to the DISICNT register.

If the DISICNT register is zero, interrupts cannot be disabled by writing a non-zero value to the register. Interrupts must be disabled by using the DISI instruction. After the DISI instruction has executed and DISICNT holds a non-zero value, the application can extend the interrupt disable time by modifying the contents of DISICNT.

The DISI Instruction (DISI) status bit (INTCON2<14>) is set whenever interrupts are disabled as a result of the DISI instruction.

Note: In the MAC class of instructions, the data space is split into X and Y spaces. In these instructions, unimplemented X space includes all of Y space, and unimplemented Y space includes all of X space.

Note: The DISI instruction can be used to disable all user interrupt sources if no source is assigned to CPU priority level 7.
53.2.4 Interrupt Operation

All interrupt event flags are sampled during each instruction cycle. A pending Interrupt Request (IRQ) is indicated by the flag bit = 1 in an IFSx register. The IRQ causes an interrupt, if the corresponding bit in the Interrupt Enable (IECx) registers is set. For the rest of the instruction cycle in which the IRQ is sampled, the priorities of all pending interrupt requests are evaluated.

No instruction is aborted when the CPU responds to the IRQ. The instruction in progress when the IRQ is sampled is completed before the ISR is executed.

If there is a pending IRQ with a user-assigned priority level greater than the current processor priority level that is indicated by the IPL<2:0> status bits (SR<7:5>), an interrupt is presented to the processor. The processor saves the following information on the software stack:

- Current PC value
- Low byte of the Processor Status register (SRL)
- IPL3 status bit (CORCON<3>)

The preceding three values allow the return Program Counter address value, MCU status bits, and the current processor priority level to be automatically saved.

After this information is saved on the stack, the CPU writes the priority level of the pending interrupt into the IPL<2:0> bit locations. This action disables all interrupts of lower or equal priority until the ISR is terminated using the RETFIE instruction.

Figure 53-2: Stack Operation for Interrupt Event

53.2.4.1 RETURN FROM INTERRUPT

The RETFIE instruction unstacks the PC return address, IPL3 status bit, and SRL register to return the processor to the state and priority level that existed before the interrupt sequence.

53.2.4.2 INTERRUPT NESTING

Interrupts, by default, are nestable. Any ISR in progress can be interrupted by another source of interrupt with a higher user application-assigned priority level. Interrupt nesting can be disabled by setting the Interrupt Nesting Disable (NSTDIS) control bit (INTCON1<15>). When the NSTDIS control bit is set, all interrupts in progress force the CPU priority to level 7 by setting IPL<2:0> = 111. This action effectively masks all other sources of interrupt until a RETFIE instruction is executed. When interrupt nesting is disabled, the user application-assigned interrupt priority levels have no effect except to resolve conflicts between simultaneous pending interrupts.

The IPL<2:0> bits (SR<7:5>) become read-only when interrupt nesting is disabled. This prevents the user software from setting IPL<2:0> to a lower value, and that effectively re-enables interrupt nesting.
53.2.5 Wake-up from Sleep and Idle

Any source of interrupt that is individually enabled using its corresponding control bit in the IECx registers can wake-up the processor from Sleep or Idle mode. When the interrupt status flag for a source is set and the interrupt source is enabled by the corresponding bit in the IEC Control registers, a wake-up signal is sent to the dsPIC33F/PIC24H CPU. When the device wakes from Sleep or Idle mode, one of the following actions will occur:

- If the interrupt priority level for that source is greater than the current CPU priority level, the processor will process the interrupt and branch to the ISR for the interrupt source.
- If the user application-assigned interrupt priority level for the source is less than or equal to the current CPU priority level, the processor will continue execution, starting with the instruction immediately following the PWRSAV instruction that previously put the CPU in Sleep or Idle mode.

**Note:** User interrupt sources that are assigned to CPU priority level 0 cannot wake the CPU from Sleep or Idle mode, because the interrupt source is effectively disabled. To use an interrupt as a wake-up source, the user application must assign the CPU priority level for the interrupt to level 1 or greater.

53.2.6 A/D Converter External Conversion Request

The INT0 external interrupt request pin is shared with the A/D converter as an external conversion request signal. The INT0 interrupt source has programmable edge polarity, that is available to the A/D converter external conversion request feature.

53.2.7 External Interrupt Support

The dsPIC33F/PIC24H supports three external interrupt pin sources (INT0-INT2). Each external interrupt pin has edge detection circuitry to detect the interrupt event. The INTCON2 register has three control bits (INT0EP-INT2EP) that select the polarity of the edge detection circuitry. Each external interrupt pin can be programmed to interrupt the CPU on a rising edge or falling edge event. For more information, see Register 53-4.
53.3 INTERRUPT PROCESSING TIMING

53.3.1 Interrupt Latency for One-Cycle Instructions

Figure 53-3 illustrates the sequence of events when a peripheral interrupt is asserted during a one-cycle instruction. The interrupt process takes four instruction cycles. Each cycle is numbered as shown in Figure 53-3.

The interrupt flag status bit is set during the instruction cycle after the peripheral interrupt occurs. The current instruction completes during this instruction cycle. In the second instruction cycle after the interrupt event, the contents of the Program Counter (PC) and Lower-Byte Status (SRL) registers are saved into a temporary buffer register. The second cycle of the interrupt process is executed as a NOP instruction to maintain consistency with the sequence taken during a two-cycle instruction (see 53.3.2 “Interrupt Latency for Two-Cycle Instructions”). In the third cycle, the PC is loaded with the vector table address for the interrupt source and the starting address of the ISR is fetched. In the fourth cycle, the PC is loaded with the ISR address. The fourth cycle is executed as a NOP instruction, while the first instruction in the ISR is fetched.

Figure 53-3: Interrupt Timing During a One-Cycle Instruction

![Diagram showing interrupt timing during a one-cycle instruction]

Peripheral interrupt event occurs at or before midpoint of this cycle

Save PC in temporary buffer

PUSH SRL and High 8 bits of PC (from temporary buffer)

PUSH Low 16 bits of PC (from temporary buffer)
53.3.2 Interrupt Latency for Two-Cycle Instructions

The interrupt latency during a two-cycle instruction is the same as during a one-cycle instruction. The first and second cycle of the interrupt process allow the two-cycle instruction to complete execution. The timing diagram in Figure 53-4 shows the peripheral interrupt event occurring in the instruction cycle prior to execution of the two-cycle instruction.

Figure 53-5 shows the timing when a peripheral interrupt coincides with the first cycle of a two-cycle instruction. In this case, the interrupt process completes as for a one-cycle instruction (see 53.3.1 “Interrupt Latency for One-Cycle Instructions”).

Figure 53-4: Interrupt Timing During a Two-Cycle Instruction

Figure 53-5: Interrupt Timing, Interrupt Occurs During 1st Cycle of a 2-Cycle Instruction
53.3.3 Returning from Interrupt

To return from an interrupt, the program must call the RETFIE instruction. During the first two cycles of a RETFIE instruction, the contents of the PC and the SRL register are popped from the stack. The third instruction cycle is used to fetch the instruction addressed by the updated program counter. This cycle executes as a NOP instruction. On the fourth cycle, program execution resumes at the point where the interrupt occurred.

53.3.4 Special Conditions for Interrupt Latency

The dsPIC33F/PIC24H allows the current instruction to complete when a peripheral interrupt source becomes pending. The interrupt latency is the same for both one-cycle and two-cycle instructions. However, certain conditions can increase interrupt latency by one cycle, depending on when the interrupt occurs. If a fixed latency is critical to the application, you must avoid the following conditions:

- Executing a MOV.D instruction that uses PSV to access a value in program memory space
- Appending an instruction stall cycle to any two-cycle instruction
- Appending an instruction stall cycle to any one-cycle instruction that performs a PSV access
- A bit test and skip instruction (BTSC, BTSS) that uses PSV to access a value in the program memory space

![Figure 53-6: Return from Interrupt Timing](image-url)
53.4 INTERRUPT CONTROL AND STATUS REGISTERS

The following registers are associated with the interrupt controller:

- **INTCON1, INTCON2 Registers**
  The following registers control global interrupt functions:
  - INTCON1 contains the Interrupt Nesting Disable (NSTDIS) bit, and the control and status flags for the processor trap sources
  - INTCON2 controls external interrupt request signal behavior and use of the alternate vector table
- **IFSx: Interrupt Flag Status Registers**
  All interrupt request flags are maintained in the IFSx registers, where ‘x’ denotes the register number. Each source of interrupt has a status bit, which is set by the respective peripherals or external signal and cleared by software.
- **IECx: Interrupt Enable Control Registers**
  All Interrupt Enable Control bits are maintained in the IECx registers, where ‘x’ denotes the register number. These control bits are used to individually enable interrupts from the peripherals or external signals.
- **IPCx: Interrupt Priority Control Registers**
  Each user interrupt source can be assigned to one of eight priority levels. The IPC registers set the interrupt priority level for each source of interrupt.
- **SR: CPU STATUS Register**
  The SR is not specifically part of the interrupt controller hardware, but it contains the IPL<2:0> Status bits (SR<7:5>), which indicate the current CPU priority level. The user application can change the current CPU priority level by writing to the IPL bits.
- **CORCON: Core Control Register**
  The CORCON is not specifically part of the interrupt controller hardware, but it contains the IPL3 Status bit, which indicates the current CPU priority level. IPL3 is a read-only bit so that trap events cannot be masked by the user-assigned application.
- **INTTREG: Interrupt Control and Status Register**
  The INTTREG register contains the associated interrupt vector number and the new CPU interrupt priority level, which are latched into Vector Number (VECNUM<6:0>) and Interrupt level (ILR<3:0>) bit fields in the INTTREG register. The new interrupt priority level is the priority of the pending interrupt.

Each register is described in detail in the following sections.

**Note:** The total number and type of interrupt sources depend on the device variant. For more information, refer to the specific device data sheet.

### 53.4.1 Assignment of Interrupts to Control Registers

The interrupt sources are assigned to the IFSx, IECx,0 and IPCx registers in the same sequence that they are listed in Table 53-1. For example, the INT0 (External Interrupt 0) source has vector number and natural order priority 0. Therefore, the External Interrupt 0 Flag Status (INT0IF) bit exists in IFS0<0>. The INT0 interrupt uses bit 0 of the IEC0 register as its Enable bit. The IPC0<2:0> bits assign the interrupt priority level for the INT0 interrupt.

- 0000001 = Interrupt Vector pending is number 9
- 0000000 = Interrupt Vector pending is number 8
53.5 INTERRUPT SETUP PROCEDURES

53.5.1 Initialization
To configure an interrupt source, perform the following:
1. If you do not use nested interrupts, set the NSTDIS control bit (INTCON1<15>).
2. Select a user-assigned priority level for the interrupt source by writing the control bits in the appropriate IPCx Control register. The priority level depends on the specific application and type of interrupt source. If you do not use multiple priority levels, program the IPCx register control bits for all enabled interrupt sources to the same non-zero value.
3. Clear the interrupt flag status bit associated with the peripheral in the associated IFSx Status register.
4. Enable the interrupt source by setting the interrupt enable control bit associated with the source in the appropriate IECx Control register.

Note: At a device Reset, the IPC registers are initialized with all user interrupt sources assigned to priority level 4.

53.5.2 Interrupt Service Routine
The method used to declare an Interrupt Service Routine (ISR) and initialize the Interrupt Vector Table with the correct vector address depends on the programming language (C or Assembler) and the language development tool suite used to develop the application. In general, the user-assigned application must clear the interrupt flag in the appropriate IFSx register for the source of interrupt that the ISR handles. Otherwise, the application will re-enter the ISR after it exits the routine. If you code the ISR in Assembler, it must be terminated using a RETFIE instruction to unstack the saved PC value, SRL value and old CPU priority level.

53.5.3 Trap Service Routine
A Trap Service Routine (TSR) is coded like an ISR, except that the code must clear the appropriate trap status flag in the INTCON1 register to avoid re-entry into the TSR.

53.5.4 Interrupt Disable
To disable interrupts, perform the following:
1. Push the current SR value onto the software stack using the PUSH instruction.
2. Force the CPU to priority level 7 by inclusive ORing the value 0xE0 with SRL.

To enable interrupts, you can use the POP instruction to restore the previous SR value.

Note: Only interrupts with a priority level of 7 or less can be disabled. Trap sources (level 8-level 15) cannot be disabled.

The DISI instruction disables interrupts of priority levels 1-6 for a fixed period of time. Level 7 interrupt sources are not disabled by the DISI instruction.
53.5.5 Code Example

Example 53-1 provides sample code that enables nested interrupts and sets Timer1, Timer2, Timer3, and change notice peripherals to priority levels 2, 5, 6 and 4. It also illustrates how interrupts can be enabled and disabled using the Status Register. Sample ISRs illustrate interrupt clearing.

Example 53-1: Nested Interrupt Code Example

```c
void enableInterrupts(void)
{
    /* Set CPU IPL to 0, enable level 1-7 interrupts */
    /* No restoring of previous CPU IPL state performed here */
    SRbits.IPL = 0;
    return;
}

void disableInterrupts(void)
{
    /* Set CPU IPL to 7, disable level 1-7 interrupts */
    /* No saving of current CPU IPL setting performed here */
    SRbits.IPL = 7;
    return;
}

void initInterrupts(void)
{
    /* Interrupt nesting enabled here */
    INTCON1bits.NSTDIS = 0;

    /* Set Timer3 interrupt priority to 6 (level 7 is highest) */
    IPC2bits.T3IP = 6;

    /* Set Timer2 interrupt priority to 5 */
    IPC1bits.T2IP = 5;

    /* Set Change Notice interrupt priority to 4 */
    IPC4bits.CNIP = 4;

    /* Set Timer1 interrupt priority to 2 */
    IPC0bits.T1IP = 2;

    /* Reset Timer1 interrupt flag */
    IFS0bits.T1IF = 0;

    /* Reset Timer2 interrupt flag */
    IFS0bits.T2IF = 0;

    /* Reset Timer3 interrupt flag */
    IFS0bits.T3IF = 0;

    /* Enable CN interrupts */
    IEC1bits.CNIE = 1;
}
```
Example 53-1: Interrupt Setup Code Example (Continued)

```c
/* Enable Timer1 interrupt */
IEC0bits.T1IE = 1;

/* Enable Timer2 interrupt (PWM time base) */
IEC0bits.T2IE = 1;

/* Enable Timer3 interrupt */
IEC0bits.T3IE = 1;

/* Reset change notice interrupt flag */
IFS1bits.CNIF = 0;

return;
}

void __attribute__((__interrupt__,__no_auto_psv)) _T1Interrupt(void)
{
    /* Insert ISR Code Here*/
    /* Clear Timer1 interrupt */
    IFS0bits.T1IF = 0;
}

void __attribute__((__interrupt__,__no_auto_psv)) _T2Interrupt(void)
{
    /* Insert ISR Code Here*/
    /* Clear Timer2 interrupt */
    IFS0bits.T2IF = 0;
}

void __attribute__((__interrupt__,__no_auto_psv)) _T3Interrupt(void)
{
    /* Insert ISR Code Here*/
    /* Clear Timer3 interrupt */
    IFS0bits.T3IF = 0;
}

void __attribute__((__interrupt__,__no_auto_psv)) _CNInterrupt(void)
{
    /* Insert ISR Code Here*/
    /* Clear CN interrupt */
    IFS1bits.CNIF = 0;
}
```
## 53.6 REGISTER MAP

A summary of the Special Function Registers associated with the dsPIC33F/PIC24H Interrupts (Part VI) module is provided in Table 53-2.

**Legend:**

- `x` = unknown value on Reset, — = unimplemented, read as '0'. Reset values are shown in hexadecimal.
Question 1: What happens when two sources of interrupt become pending at the same time and have the same user application-assigned priority level?

Answer: The interrupt source with the highest natural order priority will take precedence. The natural order priority is determined by the Interrupt Vector Table (IVT) address for that source. Interrupt sources with a lower IVT address have a higher natural order priority.

Question 2: Can the DISI instruction be used to disable all sources of interrupt and traps?

Answer: The DISI instruction does not disable traps or priority level 7 interrupt sources. However, the DISI instruction can be used as a convenient way to disable all interrupt sources if no priority level 7 interrupt sources are enabled in the user’s application.
53.8 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the dsPIC33F/PIC24H Product Family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the Interrupts module include the following:

<table>
<thead>
<tr>
<th>Title</th>
<th>Application Note #</th>
</tr>
</thead>
<tbody>
<tr>
<td>Related application notes are not available.</td>
<td></td>
</tr>
</tbody>
</table>

Note: Visit the Microchip Web site (www.microchip.com) for additional Application Notes and code examples for the dsPIC33F/PIC24H Family of devices.
53.9 REVISION HISTORY

Revision A (April 2010)

This is the initial release of this document.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Trademarks
The Microchip name and logo, the Microchip logo, dsPIC, KEELOG, KEELOG logo, MPLAB, PIC, PICmicro, PICSTART, PIC32 logo, rPIC and Uni/O are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.
FilterLab, Hampshire, HI-TECH C, Linear Active Thermistor, MXDEV, MXLAB, SEEVAL and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.
Analog-for-the-Digital Age, Application Maestro, CodeGuard, dsPICDEM, dsPICDEM.net, dsPICworks, dsSPEAK, ECAN, ECONOMONITOR, FanSense, HI-TIDE, In-Circuit Serial Programming, ICSP, Mindi, MiWi, MPASM, MPLAB Certified logo, MPLIB, MPLINK, tTouch, Octopus, Omniscient Code Generation, PICC, PICC-18, PICDEM, PICDEM.net, PICKit, PICtail, REAL ICE, rILAB, Select Mode, Total Endurance, TSHARC, UniWinDriver, WiperLock and ZENA are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.
SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.
All other trademarks mentioned herein are property of their respective companies.
© 2010, Microchip Technology Incorporated, Printed in the U.S.A., All Rights Reserved.
 Printed on recycled paper.

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOG® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
